FOREWORD

Minerals Yearbook, 1944, records another year of outstanding accomplishment by the mineral industries of the United States. For the sixth consecutive year the quantity of minerals produced has increased, and in each of the last 5 years the physical volume of production has exceeded all previous records. In 1944, for the third consecutive year, the value of production also reached a new peak. As in previous war years, this performance was made despite many difficult conditions that imposed serious restraints on production. The record of the successful prosecution of the war on the industrial front will accord high credit to the contributions of the owners, workers, and managers who have made this performance possible.

As predicted a year ago, 1943 proved to be the year in which the summit of industrial effort in this war was reached, but contrary to expectations it was not the year of maximum production and consumption for minerals. Owing to the heavy demand for fuels and a few other minerals, which moved contrary to the general trend of industrial production, the over-all trend of consumption as well as production was upward, although there were fewer increases and new records for individual commodities and considerably more decreases than in previous years. The construction phase of the war program reached a peak in 1942, and the precipitous decline noted in 1943 continued in 1944. The production of the implements of war in preparation for great offensives probably reached a peak early in 1944 although the tremendous need for replacements in the Pacific warfare and following the invasion of Europe in June 1944 maintained production at high levels. Sharp declines in war production in 1945 will be offset only in part by increasing civilian production. Industrial indexes for the first half of 1945 indicate that the total year's activity will be under that of 1944.

Victory in Europe, signalized by the surrender of the Germans at Rheims, France, on May 7, 1945, brought into sharper focus the various postwar mineral problems mentioned in the Foreword of Minerals Yearbook, 1943. No permanent solution to the difficulty presented by surplus stocks that will remain in the possession of the Government at the end of the war had been made as of July 1945. Late in 1944 Congress provided for temporary freezing of stocks of strategic and critical minerals in the Surplus Property Act approved in October, but this action expires in January 1946. Permanent stock-piling legislation has been introduced into Congress that will provide for transfer of most surpluses to permanent stock piles.

The long-range future of mineral supplies to support our vast industrial structure and high standard of living will soon command our attention instead of the shorter-term war objectives that have occupied our entire effort since 1940. The United States is by no means a "have-not" nation in minerals, but there is unmistakable

evidence that some of our commercial resources are approaching exhaustion and in others depletion is well advanced. Recognizing this situation, the Bureau of Mines is planning conversion of its wartime services to peacetime activities oriented to the broader objectives. Fortunately no drastic readjustments are required because in general the program developed during the war does not differ greatly from the Bureau's traditional peacetime activity. National defense will continue to receive serious consideration in Bureau plans. Some shift in emphasis will be required as the program is broadened to cover all industrial minerals in contrast to the very heavy emphasis on strategic and critical minerals during the war. Moreover, the program will become more national in scope as less effort will be required on purely local and temporary war problems. The Bureau's well-established services to industry will of course continue unabated and will be expanded wherever such action is advisable.

Exploration and technologic research on a broad scale are primary requirements if we are to utilize our domestic resources most effectively. To plan wisely industry must first know what we have. A reliable inventory of mineral resources is thus most essential. Efforts to achieve more efficient processing and lower costs as we are forced to operate with lower-grade materials also must be intensified. As resources play out, we should have others ready to replace them. Promotion of health and safety in the mineral industry has always been a major objective of the Bureau of Mines, and its program in this field will continue virtually without change. Similarly the Bureau's program in economics and statistics is scarcely different in war than in peace. Vast improvement has been made in the statistical program to meet war needs, and this gain fills many serious gaps that existed before the war. The Bureau plans to retain and add to these war improvements; in addition, recognizing the greater need for imported mineral raw materials and foreign markets for those minerals produced in excess of domestic needs, the Bureau's facilities for obtaining foreign statistical and other economic data will be expanded. The Bureau thus looks forward eagerly to being of more service to industry and the public and to the presentation of even more useful editions of Minerals Yearbook in the future.

The cordial cooperation of State agencies and officials is an important contribution to the Bureau's statistical program, and it is a pleasure again to acknowledge this assistance with deep appreciation. This teamwork between Federal and State agencies dates back to 1908, and many of the States have taken advantage of the cooperative agreements offered by the Bureau of Mines. By this device much economy is effected, producers and consumers of minerals are relieved of the burden of answering two sets of inquiries, and the State officials are given the detailed information supplied to the Bureau of Mines by respondents in their States. State agents cooperating in the 1944 canvass were: Walter B. Jones, State geologist, University, Ala.; Herman Gunter, State geologist, Tallahassee, Fla.; Garland Peyton, director, division of mines, mining, and geology, department of natural resources, Atlanta, Ga.; M. M. Leighton, chief, and Walter H. Voskuil, mineral economist, State geological survey division, Urbana, Ill.; A. C. Trowbridge, director, Iowa Geological Survey, Iowa City, Iowa; John C. Frye, acting director, State Geological

Survey of Kansas, Lawrence, Kans.; J. T. Singewald, Jr., director, department of geology, mines and water resources, board of natural resources, Baltimore, Md.; R. A. Smith, State geologist, Lansing, Mich.; Edward L. Clark, State geologist, Rolla, Mo.; Edward Ellingwood, chairman, New Hampshire mineral resources committee, Concord, N. H.; Meredith E. Johnson, State geologist, Trenton, N. J.; John G. Broughton, assistant State geologist, New York State Museum, Albany, N. Y.; Jasper L. Stuckey, State geologist, Raleigh, N. C.; Robert H. Dott, director, Oklahoma Geological Survey, Norman, Okla.; E. P. Rothrock, State geologist, Vermillion, S. Dak.; E. H. Sellards, director, bureau of economic geology, Austin, Tex.; Arthur Bevan, State geologist, and Linwood H. Warwick, chief clerk, Virginia Geological Survey, Charlottesville, Va.; Sheldon L. Glover, supervisor, division of mines and mining, department of conservation and development, Olympia, Wash.; R. C. Tucker, assistant State geologist, Morgantown, W. Va.; and E. F. Bean, State geologist, Madison, Wis. In addition, B. D. Stewart, department of mines, Juneau, Alaska, and Walter W. Bradley, State mineralogist, San Francisco, Calif., assisted in the compilation of statistics for Alaska and California, respectively.

The Bureau of Mines is no less appreciative of the wholehearted cooperation extended by thousands of individuals and organizations in the mineral industry, trade journals, and other Government agencies, whose generous help has made possible the preparation of this volume.

INTRODUCTION

In view of the termination of the war, Minerals Yearbook, after 3 years as a confidential volume, returns to its prewar status with the 1944 edition.

Publication of foreign-trade data and data on many strategic and critical minerals, first interrupted in the 1941 volume, was reestablished for most commodities on VE-day; and upon the formal announcement of VJ-day all remaining censorship regulations were removed, thus restoring and bringing up to date all statistical series regularly carried in Minerals Yearbook and releasing again the entire volume for public distribution.

Because of Government wartime restrictions on the publication of statistics in many countries, few figures on foreign mineral production have been available since 1939. However, with the liberation of the countries in the war zone and the easing of security regulations in many others, much data covering this 5-year period have been obtained from abroad and are included in the present volume under the respective commodity chapters.

The 1944 volume departs from the 1943 edition in but one main respect—the chapter on International Aspects of War Mineral Procurement has been greatly expanded to include a section on Foreign Minerals Review, emphasizing in particular Latin-American countries. The new section constitutes part V of the volume and will be a permanent feature of future editions.

Acknowledgments.—The Bureau deeply appreciates the warm support of the many individual mine and plant operators, distributors, consumers, public officials and agencies, trade associations, and others who have freely supplied the basic information to compile this volume.

The data on exports and imports in Minerals Yearbook were obtained through cooperation of the United States Department of Commerce.

Credit is gratefully accorded to the authors of the chapters and to many others of the Bureau's staff for their assistance and splendid cooperation in compiling, editing, and preparing the Yearbook material. Those deserving especial mention in this work are: Martha B. Clark and Marian E. Meyer, of the Economics and Statistics Branch, for preparing the statistical summary of mineral production and assuming the responsibility for the continuity of data and the uniformity of statistical presentation; Mabel E. Winslow, of the Office of Minerals Reports, for editorial supervision and constant counsel; Louis F. Perry, of the Office of Minerals Reports, and Adelaide B. Palmer, of the Economics and Statistics Branch, for the preparation of charts; and the many other members of the Economics and Statistics Branch for their assistance in the preparation of the manuscript.

C. E. NEEDHAM.

PART I. GENERAL SUMMARY

REVIEW OF THE MINERAL INDUSTRIES IN 1944¹

INTRODUCTION

The value of mineral production in the United States established a new peak in 1944 for the third consecutive year. The total value—\$8,452,000,000—was 4.7 percent above the previous peak of 1943 and 52.5 percent higher than the World War I total of \$5,540,708,000 recorded in 1918; it was 21.1 percent over the prewar high of \$6,981,340,000 established in 1920. The new record resulted from a 6.1-percent rise in the physical volume of production, as measured by Federal Reserve Board indexes, accompanied by a 2.9-percent increase in the unit sales realizations of mineral producers.

Again it is necessary to record that this unprecedented performance of the mineral industries was accomplished despite many conditions that imposed severe restraints on production. Manpower continued to be the principal bottleneck, the total labor force in the mineral industries having declined 9 percent from the already depleted supply available in 1943. By working more days and longer hours the loss in man-hours of labor was reduced to 2 percent. Lack of price incentive also was an important factor. Since 1940 mineral prices have increased only 23.2 percent, including premiums, whereas the price level of all commodities has advanced 32.3 percent and that of farm products 82.1 percent. The depleted state of our mineral reserves also prevented increases in production of some commodities. This situation is caused partly by the terrific drain on the Nation's resources that has taken place during the past 60 years and partly by the lack of development, which could not be financed during the prolonged unprofitable depression period and for which labor and equipment have not been available during the hectic war period. Other restraining factors in 1944 included transportation controls, shortages

¹ In this report the term "billion" is equivalent to 1,000,000,000.

of equipment, increasing costs, and the shut-down orders for gold and silver mines.

There was much evidence in 1944 that the Nation's war program had reached a peak on the industrial front. The Federal Reserve Board monthly index of industrial production indicates that the peak actually was reached in the latter part of 1943. The Board mineral-production index reached a high late in 1944. Consumption of many mineral commodities, particularly building materials and metals, was lower in 1944 than in 1943, but new records were made in some important fuels, in a few important metals, and in the fertilizer minerals, so that on the whole probably there was a slight net gain in consumption. Production of many minerals also declined in 1944, but these losses were more than offset by gains in the output of several important commodities. There was considerable relaxation of inventory and use controls during the year, but some of this action proved to be premature and had to be rescinded following the temporary reverses on the European front late in the year. Imports continued at a high rate, and, although Government stock-pile objectives were reduced during the year, Government inventories of many minerals increased. These gains were offset only in part by many declines in industry stocks, so that the total mineral inventory of the country increased in 1944.

Price movements, as measured by producers' unit realizations on sales, were upward, the more important gains being in fuels and other nonmetallics. An estimated 2.9-percent increase in producers' price realizations in 1944 over 1943 compared favorably with the 0.9-percent increase in the general price level as revealed by the Bureau of Labor Statistics indexes of wholesale prices. The war-inflated price of mercury was one of the first mineral prices to undergo drastic reduction as a result of an easier supply situation.

PRODUCTION

Value of mineral output.—The record established in 1944 resulted from increases in the production of mineral fuels, as the total output of metals and other nonmetallic products declined. Fuels, which comprised 61.7 percent of the total value of mineral production or \$5,212,000,000 in 1944, increased 13 percent in value in 1944 over 1943, whereas metals and other nonmetallics declined 6 and 8 percent, respectively. Metals comprised 27.7 percent of the total in 1944 and other nonmetallics 10.6 percent. The growth in value of these branches of the mineral industries since 1880 is shown in figure 1.

Contrary to the situation prevailing in recent years, the rise in the value of mineral production in 1944 compared favorably with advances in other parts of the economy. The 5-percent gain in mineral value exceeded the 3-percent increase in gross farm income as reported by the United States Department of Agriculture (\$22,775,000,000 in 1943 and \$23,446,000,000 in 1944, including Government payments). It was slightly below the 6-percent increase in gross national product from \$187,800,000,000 in 1943 to \$198,700,000,000 in 1944; war expenditures comprised 43 percent of the gross national product in 1944 and 44 percent in 1943. National income rose nearly 8 percent from \$149,400,000,000 to \$160,700,000,000, according to the United States Department

FIGURE 1.—Trends in value of mineral production in the United States, 1880–1944.

of Commerce. However, compared with 1939 the value of mineral production in 1944 had increased only 72 percent whereas gross farm income had advanced 137 percent, gross national product 124 percent, and national income 127 percent.

Failure of the mineral industry to pace other elements of the national economy may be ascribed to several factors. Some mineral commodities, such as gold, silver, and certain building materials, have been adversely affected by war conditions, so that their production has not profited from the general economic improvement. Government controls have restrained civilian and in many instances military consumption of most of the other minerals, and these restraints have been reflected in mining activity. Shortage of manpower, exhaustion or lack of resources, inadequate production capacity, and scarcity of mining equipment have prevented the domestic industry from meeting all war needs of some minerals, and the deficiencies have been made up by abnormally large importations. Copper, lead, and zinc are typical examples of this development. All these factors have retarded the advance in mineral production; and in addition, as will be shown later, the rise in the value of mineral production has been impeded by prices that consistently have been substantially below the general level.

Trends in physical volume of production.—Figure 2 compares the physical volume of mineral production during the last 45 years with industrial and agricultural production and with population growth,

each expressed in terms of an index based upon yearly averages for 1935-39.³

The long-time trends of production during this 45-year period have been steadily upward, although year-to-year and cyclical fluctuations have been prominent. Except for the last few years, the production of minerals—the essential raw materials for industry—has been closely correlated with the trend of industrial production, experiencing the

FIGURE 2.—Comparison of growth of physical volume of mineral production with that of agriculture and industrial production and population, 1900-1944.

same ups and downs, whereas agricultural production has exhibited more moderate fluctuations and a growth line approximating the trend of population increase.

Because production of coal for domestic use and of petroleum for automobile fuel (which has a pronounced effect on the trend of mineral output) does not respond proportionately to increases in the rate of manufacturing activity and is more stable, the index of industrial

³ The following indexes have been used: Volume of farm production, U. S. Department of Agriculture; mineral production, 1900-1918, Warren Persons' Forecasting Business Cycles; mineral production of 1919-44 and industrial production, Federal Reserve Board; total population of the United States, Bureau of the Census.

production tends to exceed that of mineral production in periods of prosperity and to fall below during depressions. This characteristic explains in part the wide gaps between the two indexes from 1941 to 1944. Another contributing factor is the extensive use of imported mineral raw materials in these years, which is reflected in the industrial but not in the mineral index. It should also be noted that the Federal Reserve Board index of mineral production does not include certain mineral products, such as aluminum and magnesium, while the greatly expanded war production of aircraft in which these metals are used is included in the index of industrial production.

Although the total mineral output scored a new peak in 1944, there were fewer individual commodity records than in 1943 and 1942. As in 1943, the advances in fuels weighed heavily in the total result. Production of crude petroleum increased 11 percent, natural gasoline and liquefied petroleum gases 14 percent, natural gas 11 percent, bituminous coal 5 percent, and anthracite 5 percent; all except anthracite reached new heights in 1944. The declining tempo of war production is reflected in the record of domestic metal production during the year. Among the common metals produced in quantity in the United States, manganese ore, titanium minerals, arsenic, and cadmium registered increases, and all these reached new peaks. Copper, lead, and zinc production fell 11, 8, and 3 percent, respectively, compared with 1943; manpower shortages accounted for much of these declines. Iron-ore production dropped 7 percent, and there were large decreases in the outputs of chromite, molybdenum, vanadium, and tungsten. Considerably less aluminum and magnesium was produced in 1944 than in 1943. The precious metals again fared badly; gold production decreased 27 percent and was the lowest on record since gold was discovered in California in 1848; the output of silver was 17 percent lower than in 1943. Among the more important nonmetallic mineral products barite, mica (scrap-grade), phosphate rock, potash, salt, lithium minerals, and mineral wool advanced to new highs. Production of asbestos, feldspar, slate, and sulfur advanced over 1943 but did not reach previous peaks. Production of cement, clays, gypsum, sand and gravel, stone, and other important nonmetallic commodities declined.

STOCKS

Inventory trends in 1944 presented decidedly mixed patterns, but the predominant change was upward. In those commodities of which the Government was a substantial buyer there was a notable tendency for industry stocks to decline, with gains in Government inventories more than offsetting the decline. This was true of aluminum, chromite, copper, metallurgical-grade fluorspar, Ceylon graphite, manganese ore, mercury, muscovite mica, platinum, quartz crystals, tungsten, and zinc. Industry stocks of bauxite declined, and those of Government increased, but there was a net decrease in the total. Increases in both industry and Government stocks were noted among the more important minerals only for magnesium and nickel. Decreases in both industry and Government holdings were more prevalent, such changes having been recorded for antimony, asbestos, cadmium, cobalt, synthetic and natural cryolite, acid-grade fluorspar, lead, and tin. Although Government stocks of tin concentrates increased slightly in 1944, it was evident that the United States tin position was rapidly

approaching dangerously low levels. Industry stocks of cement, iron ore, and sulfur were smaller at the end of the year than at the beginning, whereas those of anthracite, bituminous coal, ilmenite, molybdenum, and potash were larger; Government stocks of these commodities were either nil or very small. Stocks of crude petroleum were considerably lower at the end of the year than at the beginning, but this drop was partly offset by a substantial gain in refined stocks so that the net decline was relatively small.

The relaxing of inventory control measures noted in the latter part of 1943 continued in 1944, and as the war situation improved and shipping became less hazardous the War Production Board reduced its stock-pile objectives. Expectation of early termination of the war caused concern over the status of Government stocks when hostilities would cease. To prevent surplus materials from being dumped on postwar markets Congress included a temporary stock-freezing provision for strategic and critical materials in the Surplus Property Act, which it passed the latter part of 1944. These developments are discussed under the section of this chapter entitled Government Stock-Piling Activities.

CONSUMPTION

Evidence of the fact that the United States had reached its peak strength on the industrial front for this war is afforded by the record of mineral consumption in 1944. There were more decreases than increases in the use of individual commodities as compared with 1943; but because increases were recorded for most of the fuels, which comprise such an important part of the mineral total, there probably was a slight gain in total mineral consumption. The use of fertilizer minerals increased to new records in 1944, but that of metals was generally downward, the decline in ferro-alloying ores and light metals being substantial. Consumption of building materials and several of the strategic nonmetals also declined in 1944.

The Federal Reserve Board index of industrial production declined from 239 in 1943 to 235 in 1944 (1935-39 average=100) to which levels it had advanced from 89 in 1938 and 109 in 1939. The monthly record shows that the peak war production was attained in October and November 1943, when the adjusted index stood at 247; from January to December 1944 the monthly index declined from 243 to 232. The durable manufacturers index, which was 78 in 1938 and 109 in 1939, rose to 360 in 1943 and then declined to 353 in 1944. The production index for transportation equipment, including airplanes, automobiles, ships, railroad cars, and locomotives, rose from less than 100 early in 1939 to a peak of 786 in November 1943 and stood at 709 in December 1944. The heavy munitions phase of the war-production program definitely had reached its peak in 1943.

The apparent over-all increase in mineral consumption in 1944 over 1943 in the face of the 2-percent drop in industrial production may be explained by the tremendous demand for fuels and ammunition to meet the increasing activity on the fighting fronts. This would tend to increase the consumption of minerals to an extent that might more than offset the decline resulting from the tapering off in plant construction and the building of heavy war equipment which loom large in industrial production.

The more important minerals that achieved new records in consumption in 1944 included petroleum, natural gasoline, natural gas, phosphate rock, potash, nitrogen (probable), barite, sulfur, salt, lead, zinc, and manganese ore. The use of anthracite, feldspar, slate, copper, tin, and antimony was higher in 1944 than in 1943 but failed to reach new highs. Consumption of iron ore and tungsten each declined only 1 percent in 1944, but decreases in the use of many other metallic ores and metals, including chromite, molybdenum, vanadium, aluminum, bauxite, magnesium, mercury, nickel, and platinum, were considerably greater, ranging from 5 to 30 percent. Steel production increased slightly to a new peak; as a result, consumption of iron ore and manganese ore was maintained at high levels, but the 19-percent decline in the production of alloy steels was reflected in a sharp falling off in the use of other major ferro-alloying minerals. Despite the record output, there was a slight decrease in the domestic consumption of bituminous coal as a result of increased demand for bunker and export fuel and continued rationing at home.

Building activity continued the sharp decline noted in 1943 following the completion of a large part of the industrial plant expansion and military cantonment construction programs. According to the United States Department of Commerce, the total value of all new construction put in place in continental United States during the year was \$3,935,000,000, a 49-percent decline from \$7,675,000,000 in 1943 and a 77-percent drop from the peak of \$17,379,000,000 in 1942; the value in 1938 was \$5,254,000,000. The major declines in 1944 were in military, naval, and public industrial construction. Highway and public and private residential building also declined, but signs of re-conversion were noted in the increase in privately financed industrial, farm, and public utility construction. As a consequence of these reductions, consumption of building materials of mineral origin, including cement, clays, sand and gravel, and stone, were considerably lower in 1944 than in previous recent years. The consumption of lime declined only slightly, that of gypsum was virtually the same as in 1943, and that of slate increased slightly.

PRICES

Average mineral prices in 1944 advanced more than the general price level. An index of producers' unit realizations on 24 minerals that represent over 96 percent of the value of mineral production, weighted according to 1940 production, showed an average increase of 2.9 percent over 1943. Bureau of Labor Statistics indexes of wholesale prices for all commodities and for farm products each increased less than 1 percent. However, during the entire war period prices for minerals have advanced much less than those of other commodities. Since 1940 unit price realizations for minerals have increased only 23.2 percent, whereas prices for all commodities have risen 32.3 percent and those of farm products 82.1 percent. These computations for minerals include premium prices paid for copper, lead, and zinc but do not include the transportation subsidies paid by the Government on other commodities.

Fuels prices have fared better than other mineral prices during the war. Since 1940 the weighted average price realization by producers of 5 mineral fuels has increased 27.5 percent; 1944 averages were 4

percent over those in 1943. Average prices for 10 metals rose 18.3 percent from 1940 to 1944 but only 1 percent from 1943 to 1944. The index of prices for 9 nonmetallic minerals other than fuels advanced 14.4 percent from 1940 to 1944 and 2.1 percent from 1943 to 1944.

There were few changes in ceiling prices in 1944. Of particular significance were those for coal granted as a result of wage increases. Prices for most metals were virtually unchanged in 1944. Ceilings for copper, lead, and zinc were maintained at 1943 levels, but a larger proportion of the domestic production came under premium prices, so that the average prices realized by producers were substantially higher. The average value of petroleum at the well was only slightly higher in 1944 than in 1943, but there was an appreciable rise in the estimated value of natural gas and natural gasoline at producing centers. With the exception of sand and gravel and natural and petroleum asphalts, prices of which were lower, producers of nonmetallics received slightly higher or the same unit returns in 1944 as in 1943. The outstanding decline in 1944 was in the price of mercury, which followed a sharp drop in demand and the entrance of European mercury in the domestic market in quantity for the first time since 1941. Producers of tungsten also received less for their product in 1944 than in 1943.

The Bureau of Labor Statistics index (1926=100) of wholesale prices for all commodities rose from 78.6 in 1940 to 103.1 in 1943 and 104.0 in 1944. The index for farm products was 67.7 in 1940, 122.6 in 1943, and 123.3 in 1944 and showed the greatest rise during the war period of any major group of commodities. The fuel and lighting index increased from 71.7 in 1940 to 80.8 in 1943 and 83.0 in 1944; the index for anthracite rose from 90.4 in 1943 to 95.6 in 1944, that for bituminous coal from 116.1 to 120.3, coke from 122.7 to 130.3, and petroleum and products from 62.5 to 63.9. The metals and metal products index was 103.8 in 1944 and 1943 compared with 95.8 in 1940; fabricated products weigh heavily in the computation of indexes for this group. In the building materials field, for which the group index showed a better than average rise in 1944—115.5 compared with 111.4 in 1943 and 94.8 in 1940—gains over 1943 were noted for brick and tile, and cement. The price index for fertilizer materials was 81.3 in 1944, 80.0 in 1943, and 69.4 in 1940.

EMPLOYMENT

In 1944 approximately 11,000,000 men were in the armed forces, and with heavy production schedules to be met by American industry acute labor shortages were the order of the day. Even in those mining and refining industries in which production requirements declined, operators had difficulty in hiring and holding enough manpower to meet the demand. The total labor force in the mineral industries has dropped steadily from 835,183 men in 1941 to 763,320 in 1943 and 693,800 in 1944. Reduction in the number of employees has been compensated to some extent by working the available men more and longer days. Workdays per employee increased from an average of 279 in 1943 to 285 in 1944 and hours from 2,104 to 2,264. Total man-days were 7 percent lower than in 1943, but total man-hours declined only 2 percent.

Selective Service continued to take many of the younger men. In order to maintain high output of minerals, a policy favoring the deferment of miners was in force at the beginning of the year, but when the

need for combat replacements increased, a more stringent policy was adopted. Deferments of men under 30, particularly those under 26, were reviewed, and many were taken. In response to protests from employers, a new list of "supercritical" activities was drawn up by an Inter-Agency Committee and used by Selective Service as a guide in granting deferments to men under 26. At that time the agencies represented considered that supplies of metals and minerals were adequate, and further deferment preference was not warranted. However, on the recommendation of the War Manpower Commission, coal miners under 26 were deferred, owing to the serious threat of a severe coal shortage. Fortunately the Army and Navy had reached approximately their enlistment goals so total monthly quotas were comparatively low and the heavy withdrawals from the age groups under 26 were compensated by fewer inductions above that age. Under these conditions withdrawals from the mineral industries were serious but not as severe as had been anticipated.

Inductions into the services have increased the average age of workers substantially. In 1944 the War Manpower Commission reported that in the past 2 years the average age of coal miners had increased from 32 to over 40.

Responsibility for labor distribution was vested in the War Manpower Commission. In the mineral industries, it had the greatest difficulty in maintaining an adequate labor force in the coal industry. During most of the year the shortage was estimated to be between 30,000 and 40,000 men. Recruiting campaigns, training programs, assistance with deferments, interchange of information on efficient manpower utilization, and preferential reference of available men were among the methods used to supply men to essential operations. On July 1, 1944, the War Manpower Commission established a Nation-wide system of labor priority referrals, which provided that employers should hire male workers only from those referred by the United States Employment Service. Under this plan each plant was given a priority rating and USES channeled workers into essential and locally needed activities in the order of their relation to the war program.

Congress seriously considered several bills, some of which were actively supported by the War and Navy Departments, that would have established various forms of national labor service, particularly for men of draft age who had been rejected for military service. This movement met strong opposition from labor and other groups and was finally abandoned.

Although relatively few in number compared with the men taken by Selective Service, some veterans were released from military service and returned to their old or to new jobs. As their total became appreciable and the prospect of much greater numbers loomed in the future, Selective Service outlined the methods by which local draft boards are to assist the return of veterans to civil life. Local boards are responsible for protection of the reemployment rights of veterans and also will assist them in obtaining other positions through the USES if they do not wish to return to previous employers.

As victories on the battlefields indicated that the war was approaching conclusion, Congress turned its attention to reconversion. The prospect of temporary or prolonged unemployment ranks high among

the critical problems anticipated. After debating the merits of Federal versus State supervision of unemployment compensation Congress passed the George bill establishing the Office of War Mobilization and Reconversion that is to have general powers over the reconversion program. This law provides that unemployment compensation is to be administered by the States according to their individual rules, but a Federal fund is made available for interest-free loans to the States to insure the solvency of their unemployment funds.

With the gradual increase in the cost of living, the pressure for compensating wage adjustments has become more intense. In 1944, negotiations between coal-mine operators and miners were so prolonged that the threat of a strike of indefinite duration forced the Government to assume control of the mines for several months. Efforts to induce the War Labor Board to revise the Little Steel Formula were unsuccessful, but within its framework many wage increases were granted. One of the most significant of these was the "portal-to-portal" pay approved as one of the provisions of the wage agreement in the bituminous-coal industry. The validity of this principle has been tested in the courts and reaffirmed.

Another trend of more than current interest is the development of foremen's unions. Historically, foremen have been considered to be representatives of management and therefore not eligible to organize under the National Labor Relations Act. A body of opinion now holds that foremen are essentially employees and as such they can organize for collective bargaining under the act. The movement has become strong enough in the mining industry so that a strike of supervisors forced the Government to seize coal mines to prevent a serious interruption of output. At the end of the year the status of foremen's unions was being studied by both the National Labor Relations Board and the National War Labor Board.

In accordance with the provisions of the Fair Labor Standards Act, on March 22, 1944, the United States Department of Labor established a minimum wage of 40 cents per hour for the metal ore, coal, petroleum, and natural gas industries.

SAFETY

The over-all safety record of the mineral industries in the United States improved in 1944 and was appreciably more favorable than in any year since the start of complete injury statistics on mining and quarrying in 1930. The record in 1944 was attained despite such war-time handicaps as loss of skilled workers to the armed forces, maintenance of production at high levels with a reduced labor force, and the tiring effects of the longer workdays and work year on employees. A combined frequency rate of fatal and nonfatal injuries of 56.01 per million man-hours of exposure to hazards was achieved in 1944 by the estimated total of 693,800 employees who worked slightly more than $1\frac{1}{2}$ billion man-hours in 1944. The corresponding rate in 1943 was 56.85 and in 1934 76.81. Fatal injuries in 1944 occurred at a rate of 1.00 and nonfatal injuries at a rate of 55.01 per million man-hours of exposure. These frequencies also were lower than the corresponding rates in any year since the statistical series began in 1930.

Preliminary figures indicate that accidents during 1944 resulted in injury to 87,954 employees, approximately 3,400 fewer injuries

than occurred in 1943. In 1944 there were 86,391 nonfatal injuries that disabled the worker for longer than the day on which the accident occurred. Fatal injuries during the year totaled 1,563. During 1944, there were four major disasters in which 94 men lost their lives—22 in explosions of gas or dust and 72 in mine fires. All occurred in bituminous-coal mines. In 1943, 161 lives were lost in 7 major disasters.

The safety record in 1944 in the coal-mining industry made the greatest improvement over 1943 of any of the mineral industry groups. This improvement is of special significance because fewer workers in the bituminous-coal mines increased production to a record annual total in 1944 and likewise a reduced labor force in the anthracite industry produced more coal than in 1943. In the metal- and non-metal-mining groups, the injury records also were more favorable than in 1943. The moderate improvement in metal mines resulted from lower frequencies of injuries during 1944 in copper, gold, and silver lode mines and miscellaneous metal mines. The injury-frequency rates of the quarry and coke industries were higher in 1944 than in 1943. In metallurgical plants the over-all safety record was only slightly less favorable than in 1943, owing to a slightly higher frequency of injuries in smelters and associated works which was not compensated entirely by the improvement in mineral-dressing mills and associated works.

GOVERNMENT STOCK-PILING ACTIVITIES

Stock-piling for war.—Favorable developments on the battle fronts have been reflected in changes in the stock-pile objectives established by the war agencies. Early in the war Government stock-pile goals for some strategic and critical materials were set as high as a full 3-year emergency supply. Few if any of these were ever reached, but by August 1943 the war outlook had improved to a point where the War Production Board felt justified in reducing the objectives to a 1-year supply. A factor contributing to this decision was the growing alarm at the mounting stocks which constituted a threat to raw material markets should they be dumped at the termination of the war. In February 1944 the War Production Board again reduced its goals to 3 months' total requirements or 1 year's requirements less anticipated North American production, whichever was higher.

On October 31, 1944, a further reduction to 3 months' total requirements or 6 months' imports, whichever was greater, was adopted. At the same time the stock-pile formula, which heretofore had included only Government-owned material, was broadened to include industry stocks in excess of safe working inventories. This policy prevailed until after V-E day, when the increase in the territory from which strategic materials could be obtained, the reduction of war hazards to shipping, and lower military requirements made possible a further reduction of stock-pile objectives. In June 1945 the War Production Board abandoned the total requirements base and authorized goals equivalent to only 3 months' military requirements at the rates established in the second quarter of 1945. The new formula applied only to Government-owned inventories. Provision was made as usual for special treatment of exceptional cases.

Although the trend of Government stocks of most minerals was upward during 1944, inventories of several commodities were lower at the end of the year than at the beginning. Substantial reductions are anticipated in 1945.

Stock-pile legislation.—None of the stock-piling bills introduced and considered by the Seventy-eighth Congress was enacted into law. (See Minerals Yearbook, 1943.) However, the Surplus Property Act of 1944, approved October 3, 1944, contained a stock-piling provision designed to freeze in permanent stock piles the surplus stocks of strategic and critical materials on hand at the end of the war. Section 22 of the act reads as follows:

(a) All Government-owned accumulations of strategic minerals and metals, including those owned by any Government corporation, shall be transferred by the owning agency, when determined to be surplus pursuant to this Act, to the account of the Treasury Procurement Division and shall be added to the stock pile authorized by the Act of June 7, 1939 (53 Stat. 811), as amended, and shall be subject to its provisions: *Provided*, That contractor inventory shall be so transferred only when the owning agency has taken possession of and determined such inventory to be surplus. The minerals and metals may be transferred in any form in which they are held, but the owning agency or the Treasury Procurement Division is authorized either before or after such legal transfer to cause such minerals or metals to be put into forms best suited for storage and use for the common defense. As used in this section the phrase "strategic minerals and metals" means copper, lead, zinc, tin, magnesium, manganese, chromite, nickel, molybdenum, tungsten, mercury, mica, quartz crystals, industrial diamonds, cadmium, fluor spar, cobalt, tantalite, antimony, vanadium, platinum, beryl, graphite (and to which may be added aluminum or any other minerals or metals in such quantities or amounts as the Army and Navy Munitions Board may determine to be necessary for the stock pile authorized by the Act of June 7, 1939), and shall include ores, concentrates, alloys, scrap, and partially and completely fabricated articles of which the principal components by value consist of such minerals and metals, but shall not include such fabricated articles as the Army and Navy determine are not suitable for their use in the form in which fabricated and which may be disposed of commercially at value substantially in excess of the metal market price of the component minerals and metals of such fabricated articles.

(b) Pending a determination by the War Production Board that the supplies of the respective strategic minerals and metals available to industry are sufficient to meet the current requirements of industry, the owning agency subject to the regulations prescribed by the Surplus Property Board shall withhold from transfer under this section an amount of such minerals and metals equal to the deficiency, if any, estimated by the War Production Board as likely to exist for the requirements of industry for a period of six months for purposes other than war production; and may dispose of the minerals and metals so withheld to the extent necessary to meet any such deficiency actually found to exist by the War Production Board, at the market price of the respective minerals and metals.

(c) Any Government-owned accumulations of strategic materials shall at the request of the War and Navy Departments be transferred by the owning agency, when determined to be surplus pursuant to this Act, to the account of the Treasury Procurement Division and shall be added to the stock pile authorized by the Act of June 7, 1939 (53 Stat. 811), as amended, and shall be subject to its provisions. The materials may be transferred in any form in which they are held and they shall thereafter be put into forms best suited for storage and use for the common defense. The term "strategic materials" as used in this subsection means all materials except strategic minerals and metals as defined in subsection (a) of this section and includes all materials in group A or in group B of the list of strategic and critical materials determined upon by the Army and Navy Munitions Board on March 6, 1944, as amended from time to time, but shall not include any of such materials which the Army and Navy determine do not meet the specifications suitable for common defense or are in excess of the needs thereof. The Army and Navy Munitions Board is authorized to direct the removal from the list of any of the materials as defined in this subsection, in which event they shall be disposed of under the provisions of this Act.

(d) Within three months following the enactment of this Act the Army and Navy Munitions Board shall submit to Congress its recommendations respecting

the maximum and minimum amounts of each strategic mineral or metal which in its opinion should be held in the stock pile authorized by the Act of June 7, 1939. After one year from the submission of such recommendations, unless the Congress provides otherwise by law, the Board may authorize the proper disposal agencies to dispose of any Government-owned accumulations of strategic minerals and metals including those owned by any Government corporation when determined to be surplus pursuant to this Act.

This bill generally was regarded as a stop-gap measure to prevent dumping of surplus stocks should the war terminate before permanent stock-pile legislation was enacted. Paragraph (d) of section 22 limits the mandatory transfer of inventories to a period ending 1 year after the submission of the Army and Navy Munitions Board report on minimum and maximum stock-pile requirements. This report was submitted on January 2, 1945 (S. Doc. 5, 79th Cong., 1st sess.), so that after January 2, 1946, the transfer of surplus stocks to permanent stock piles is left to the discretion of the Surplus Property Board. As of July 1945 no material had yet been declared surplus or added to the permanent stock piles, and the outlook for any appreciable contribution to the solution of the postwar strategic material problem under this act was unfavorable.

In March 1945 identical bills, S. 752 and H. R. 2624, were introduced into the Senate and the House of Representatives by the chairman of the respective Military Affairs Committees. These bills would establish a permanent stock-piling program, including the freezing of postwar surplus stocks of strategic and critical materials, the procurement of adequate additional supplies after the war, and the encouragement of the conservation and development of sources of these materials within the United States. Hearings are planned for the fall of 1945, and as of July the bills were being studied by the executive departments of the Government.

Army and Navy Munitions Board Report.—In preparing the report on minimum and maximum stock-pile requirements called for in section 22 (d) of the Surplus Property Act of 1944 (Public Law 457, 78th Cong.), the Army and Navy Munitions Board, with the concurrence of the Secretary of the Interior, presented a detailed analysis of the strategic material problem. The report outlines the needs for stock-piling, the development of stock-pile policy, and the accomplishments under the wartime program. Although the minimum and maximum stock-pile objectives were not made public for reasons of security, the principles upon which they were determined and the lists of strategic and critical materials were given in the report. The definitions and lists as approved by the Board on November 20, 1944, were as follows:

Current list of strategic and critical materials

(The following forms an inseparable part of the strategic and critical materials list)

1. The definition of strategic and critical materials is as follows: "Strategic and critical materials are those materials required for essential uses in a war emergency, the procurement of which in adequate quantities, quality, and time is sufficiently uncertain for any reason to require prior provision for the supply thereof."

2. Within the above definition, materials are listed either in group A, group B, or group C, according to the following provisions:

(a) Group A comprises those strategic and critical materials for which stock-piling is deemed the only satisfactory means of insuring an adequate supply for a future emergency.

(b) Group B comprises additional strategic and critical materials, the stock-piling of which is practicable. The Army and Navy Munitions Board recommends their acquisition only to the extent they may be made available for transfer from Government agencies because adequacy of supply can be insured either by stimulation of existing North American production or by partial or complete use of available substitutes.

(c) Group C comprises those strategic and critical materials which are not now recommended for permanent stock-piling because in each case difficulties of storage are sufficient to outweigh the advantages to be gained by this means of insuring adequate future supply.

3. Materials in group A may be acquired in the manner prescribed for group B. Materials in all three groups are subject to constant surveillance and review. Additions to, or deletions from, the list, or movement of materials between groups, may be made, based upon future changes in their strategic and critical status.

4. The conduct of a war requires the use of an encyclopedic list of semiprocessed and processed materials, such as aviation gasoline, synthetic rubber, chemicals, drugs, ferroalloys, steel, light metals, etc. Elevation from peacetime production to a wartime footing will necessitate constant review of the facilities available to meet anticipated requirements.

GROUP A

Agar.
Antimony.
Asbestos:¹
 Rhodesian chrysotile.
 South African amosite.

Bauxite.

Beryl.

Bismuth.

Cadmium.

Castor oil.²

Celestite.

Chromite:

 Metallurgical grade.

 Refractory grade:

 Rhodesian origin.

 Other origin.

Cobalt.

Coconut oil.²

Columbite.

Copper.

Cordage fibers:²

 Manila.

 Sisal.

Corundum.

Diamonds, industrial.

Emetine.

Graphite:

 Amorphous lump.

 Flake.

Hyoscine.

Iodine.¹

Jewel bearings:

 Instrument jewels, except V jewels.

 Sapphire and ruby V jewels.

 Watch and timekeeping device jewels.

Kapok.²

Kyanite, Indian.

Lead.

Manganese ore:

 Battery grade.

 Metallurgical grade.

Mercury.

Mica:

 Muscovite block and film, good stained and better.

 Muscovite splittings.

 Phlogopite splittings.

Monazite.

Nickel.

Opium.¹

Optical glass.

Palm oil.²

Pepper.

Platinum group metals:

 Iridium.

 Platinum.

Pyrethrum.²

Quartz crystals.

Quebracho.

Quinidine.

Quinine.¹

Rapeseed oil.²

Rubber:^{1,2}

 Crude rubber.

 Natural rubber latex.

Rutile.

Sapphire and ruby.

Shellac.²

Sperm oil.²

Talc, steatite, block or lava.

Tantalite.

Tin.

Tung oil.²

Tungsten.

Vanadium.

Zinc.

Zirconium ores:

 Baddeleyite.

 Zircon.

¹ Require special storage conditions.

² Require rotation of stocks.

³ Stocks to be held by Treasury Department, Bureau of Narcotics.

GROUP B

Aluminum.
Barite.
Chalk, English.
Chromite, chemical grade.
Cryolite, natural.
Diamond dies.
Emery.
Fluorspar :
 Acid grade.
 Metallurgical grade.
Graphite, crystalline fines.
Magnesium.¹

Mica :
 Muscovite block, stained and lower.
 Phlogopite block.
Molybdenum.
Platinum group metals :
 Osmium.
 Palladium.
 Rhodium.
 Ruthenium.
Selenium.
Talc, steatite, ground.
Wool.^{1,2}

GROUP C

Asbestos, Canadian chrysotile.¹
Bristles, pig and hog.¹
Burlap, jute.⁴
Cordage fibers :²
 Hemp, true American.
 Henequen.
 Jute.
Cork.³
Iron ore.
Leather :^{1,2}
 Cattle hides :

 Heavy.
 Light.
 Calf and kip skins.
Loofa sponges.¹
Lumber :
 Balsa.
 Mahogany.
Petroleum and petroleum products.^{1,2}
Radium.^{1,2}
Scrap, iron and steel.
Sesame oil.²

The minimum quantities of group A materials recommended for stock-piling were computed on the basis of certain strategic assumptions determined by the Joint Chiefs of Staff and the United States consumption (including military, lend-lease, and essential civilian requirements) during the peak year of the present war. In addition, the figures reflected the following considerations :

- (a) Compensation for any known depletion of, or reasonably certain increases in, available resources in the United States ;
- (b) A similar compensation for known anticipated changes in resources of material outside the United States (as to which we have comparatively meager information at the present time) ;
- (c) Adjustment for anticipated increases or decreases in future military requirements as the result of technological changes already evident ;
- (d) Adjustments wherever consumption data indicate that it has been necessary to use inferior grades of material in the present war ; and
- (e) Limitations imposed upon the stock piles of perishable materials by reason of the necessity of rotating the quantities involved.

The maximum quantities of group A materials were determined on the basis of the following additional considerations needed to provide additional security.

- (a) Supply from foreign sources as it may be affected in a future emergency by international political and economic conditions ;
- (b) The inordinate expenditures of manpower, equipment, and money which may be required to build up supplies of certain materials ;
- (c) Maintenance of an industrial economy at a higher level of efficiency than that prevailing during the current emergency by minimizing drastic dislocations resulting from critical shortages ; and
- (d) Requirements as they may be affected by the civilian needs of a population of the United States larger than the present population.

¹ Require special storage conditions.
² Require rotation of stocks.

The minimum quantities recommended for group B materials were zero because supplies could be assured by means other than stock-piling. Maximum quantities were established on the basis of considerations similar to but not identical with those used for calculating group A maximums.

The report wisely calls attention to the fact that within practical limits the larger the stock pile, the greater degree of security provided. The maximum quantities recommended for nonperishable items represent the largest quantities for which the Board felt the expenditure of public funds was justified.

The report also emphasizes the need for constant review and revision of strategic and critical lists and stock-pile objectives to reflect changes in technology and shifts in political and economic factors that affect the strategic status of raw materials.

The following suggestions as to future stock-pile legislation were offered:

We recommend that the Congress adopt further stock-piling legislation in order to eliminate certain undesirable features of established policies relating to the procurement and release of materials for Government stock-piling. In view of the substantial depletion of domestic resources during the present war, statutory domestic preference requirements, allowing a year for deliveries from domestic production and the preference for domestic materials, as provided in the act of June 7, 1939, and the Buy American Act, respectively, are too restrictive. We believe that these requirements must be relaxed. Provision should also be made to permit the disposal of materials in stock piles which have become obsolete, due to technological developments, as well as to permit rotation of those which are subject to deterioration.

We further emphasize that the acquisition of stock piles in even the minimum quantities recommended in this report must be a gradual process, and will require periods ranging from 1 to 10 years, depending upon the material to be accumulated. This is because production of some of the materials in normal times is little beyond normal requirements of peacetime industry. In view of this fact, and the likelihood that in a future war we shall not have the time required to make the necessary provision for materials, it is important that an early beginning be made toward accomplishing a sound stock-pile program.

Closely related to stock-piling are several other measures that should be given consideration in connection with any plan for the supply of strategic materials in war. On account of the direct bearing which these measures have on the kinds and quantities of materials that should be stock piled, it seems appropriate to include them under these suggestions for future legislation. We refer to provisions for stand-by facilities, pilot-plant operations, continuous technological research, and the development of more economical processes for the utilization of domestic marginal resources.

GOVERNMENT ORGANIZATION FOR WAR

Recent editions of Minerals Yearbook have presented a brief summary of the Government agencies administering the war program with a view to preserving a chronological record of the major changes in organization and key personnel that affect the mineral industries. Minerals Yearbook, 1943, presented the story up to July 1944, and this review carries the record forward to July 1945. Details of the various actions taken by these agencies are given in the commodity chapters of this volume.

Although there were many internal changes in the organization and personnel of the war agencies in the latter half of 1944 and the first half of 1945, there were few significant modifications, and those were concerned chiefly with the approaching problems of reconversion. The Office of War Mobilization and Reconversion was estab-

lished as an independent agency pursuant to an act of Congress approved October 3, 1944. The new agency, which absorbed the functions of the Office of War Mobilization created by Executive order on May 27, 1943, is responsible for the development of unified programs and the establishment of policies for the maximum use of the Nation's resources, including civilian manpower; the unification of the activities of the Federal agencies concerned with the production, procurement, distribution, or transportation of supplies and materials; the issuance of such directives to Federal agencies as appear necessary to the conduct of the war; and the formulation of plans and the issuance of such orders as are required to meet the problems arising from the transition from war to peace. In effect the agency was charged with supervision of the activities of all Government agencies dealing with war production, civilian manpower, the civilian economy, and reconversion. James F. Byrnes was named Director, with Fred Searls, Jr., Deputy Director for Production Liaison and Coordination. Byrnes resigned in April 1945 and was succeeded by Fred M. Vinson. John W. Snyder replaced Vinson in July 1945 when the latter was appointed Secretary of the Treasury.

The Surplus Property Act of 1944, approved October 3, 1944, established a Surplus Property Board of three members within the Office of War Mobilization and Reconversion. The act also prescribed the principles that would guide the disposal of surplus property after the war. The Board was authorized to provide general supervision and direction over the care, handling, and disposition of surplus property, including stocks of strategic and critical minerals and Government-owned metal and mineral processing plants, and the transfer of surplus property between Government agencies. Guy M. Gillette was appointed Chairman of the Board and Robert A. Hurley and Edward H. Heller members. Mason Britten was appointed Administrator for the Board. The functions of the Surplus War Property Administration, created by an Executive order dated February 21, 1944, were transferred to the new Board. Prior to the transfer W. L. Clayton, Administrator, and G. Temple Bridgman, Deputy Administrator, had resigned from the Surplus War Property Administration. After a few months' service Gillette announced his desire to resign, stating that the Surplus Property Act required revision if the Board were to become an effective organization. Among the changes recommended were that the Board be replaced by a single surplus-property administrator and that real surplus-property-disposal authority be placed in an agency independent of the Office of War Mobilization and Reconversion. In July 1945, W. Stuart Symington was confirmed as the new Chairman of the Board, and legislation was introduced into Congress to amend the Surplus Property Act along lines suggested by Gillette.

Other recent major developments include the resignation of Donald H. Nelson, who had held a prominent position in the defense and war programs since 1940, as Chairman of the War Production Board and the appointment of J. A. Krug as his successor; the reestablishment of the Federal Loan Administration as an independent agency and the appointment of Fred M. Vinson as Administrator (later succeeded by John W. Snyder); the appointment of William H. Davis, formerly Chairman of the National War Labor Board, as Director of the Office of Economic Stabilization, vice Vinson; and the appoint-

ment of George W. Taylor to the chairmanship of the National War Labor Board. Other changes in the organizations chiefly concerned with the mineral activities of the war program are recorded below.

War Production Board.—Changes in the War Production Board since June 1944 have been chiefly in personnel; organization changes have been relatively unimportant. In July 1944 James Douglas, formerly Director of the Zinc Division, succeeded Howard I. Young as Deputy Vice Chairman for Metals and Minerals Production and also took over direction of the Mineral Resources Coordinating Division and the chairmanship of the Minerals and Metals Advisory Committee, the Mineral Resources Operating Committee, and the Mineral Classification Committee. The Zinc Division was then merged with the Tin-Lead Division under Erwin Vogelsang, Director, with Myron L. Trilsch Deputy Director for Zinc. George C. Heikes, formerly Director of the Zinc Division, was recalled in July as Director of the Aluminum-Magnesium Division; T. E. Covel was named Deputy Director in October. Heikes resigned in March 1945 and was succeeded by Nigel H. Bell. Also in July 1944 the War Production Board announced the appointment of Dr. Donald B. Keyes as Director of the Office of Production Research and Development, vice Harvey N. Davis who resigned.

A major shake-up occurred the latter part of August following rumors of dissension in the top command. Executive Vice Chairman Charles E. Wilson resigned, Chairman Donald M. Nelson was sent on a special mission to China, and J. A. Krug was named Acting Chairman. Nelson's resignation was accepted early in October, and Krug was named Chairman.

Early in September L. R. Boulware, Operations Vice Chairman, returned to industry and was succeeded by Hiland G. Batcheller, who had resigned from the same post in November 1943. On September 1, Richard J. Lund, Director of the Miscellaneous Minerals Division, resigned, and James S. MacGregor, Deputy Director, was elevated to the post. At the end of May 1945 MacGregor returned to private life and was succeeded by F. G. Rockwell, then Deputy Director. Later in September Krug announced that Deputy Executive Vice Chairman Arthur H. Bunker had been shifted to the position of Chief of Staff and Batcheller had been named Chief of Operations. These changes were announced as major moves in the streamlining of the Board's organization to deal with reconversion. Harold Boeschstein later became Operations Vice Chairman, and Bunker stepped out in December. Bunker's position was not filled until May 1945, when John D. Small, who had been serving as Executive Officer of the Board, was appointed to the post.

M. H. Billings, Director of the Mica-Graphite Division, left the War Production Board in October, whereupon the Division was consolidated with the Miscellaneous Minerals Division. Stacy May, Chief of the Bureau of Planning and Statistics (subsequently renamed Bureau of Program and Statistics), returned to private employment October 1 and was replaced by Bertrand Fox.

The Quota Committee for the Premium Price Plan was reorganized in November to provide a nonvoting Chairman. The Committee continued as before with 6 voting members—3 from the War Production Board and 3 from the Office of Price Administration. Ellsworth R. Bennett was appointed Chairman, and Landon Strobel was retained

as Executive Secretary. Frank H. Hayes, the former Chairman, was elevated to the post of Assistant Director of the Copper Division in charge of production. He continued temporarily as a voting member of the Committee but was succeeded in December by Edward J. Craig as the representative of the Copper Division. Bennett returned to the mining industry in May 1945 and was succeeded by Roland D. Parks, who continued also to serve as Assistant Deputy Vice Chairman for Production.

In December the Mineral Resources Coordinating Division was abolished as an organizational unit, and its functions were transferred to the Office of the Vice Chairman. Wilbur A. Nelson, who had served as Deputy Director of the Division, resigned to enter private employment.

Indicative of the extent to which Government action in the industrial field had diminished was the announcement that the staff of the Steel Division had been reduced from a peak of 800 to less than 250 on November 30. During the past year the Division organization has been simplified. In December William F. Todd succeeded Norman W. Foy, who resigned as Director but later returned as a special assistant to the Chairman of the Board. H. M. Francis was made Deputy Director.

Late in February Philip D. Wilson, who had succeeded Bunker as Vice Chairman for Metals and Minerals in June 1944, was shifted to a position of Special Assistant to the Chairman; W. C. Keeley assumed the vacated post. Early in May the resignations of Wilson and S. W. Anderson, Program Vice Chairman, were announced, Lincoln Gordon taking the latter's place. Near the end of June the appointment of R. C. Allen as Deputy Vice Chairman for Metals and Minerals was announced, and 2 weeks later he was designated Vice Chairman, succeeding Keeley, who returned to industry. Allen previously had served over 2 years in the War Production Board and its predecessors, having resigned the post of Deputy Director of the Steel Division in charge of raw materials in August 1942.

As of July 1945, the members of the War Production Board and the principal staff officers dealing with policy or administration affecting the mineral industries were as follows:

WAR PRODUCTION BOARD

Members

Chairman.....	J. A. Krug.
Secretary of War.....	Henry L. Stimson.
Secretary of the Navy.....	James Forrestal.
Secretary of Agriculture.....	Clinton P. Anderson.
Federal Loan Administrator.....	Vacancy.
Administrator, Office of Price Administration.....	Chester Bowles.
Foreign Economic Administrator.....	Leo T. Crowley.
Chairman, War Manpower Commission.....	Paul V. McNutt.
Director, Office of Defense Transportation.....	J. M. Johnson.
Petroleum Administrator for War.....	Harold L. Ickes.
Director of Contract Settlement.....	Robert H. Hinckley.

Staff

Chief of Staff.....	John D. Small.
Assistant to the Chairman.....	Charles H. Ketcham.
Office of Production Research and Development, Director.....	Donald B. Keyes.
Metals and Minerals Branch, Chief.....	C. K. Leith.

WAR PRODUCTION BOARD—Continued

Staff—Continued

Bureau of Program and Statistics, Director.....	Bertrand Fox.
Office of War Utilities, Director.....	Edward Falck.
Vice Chairman for Smaller War Plants.....	Maury Maverick.
Vice Chairman for Civilian Requirements.....	W. Y. Elliott.
Program Vice Chairman.....	Lincoln Gordon.
Vice Chairman for Field Operations.....	James A. Folger.
Vice Chairman International Supply.....	William L. Batt.
Division of Stock-piling and Shipping, Chief.....	Morton Banks.
Vice Chairman for Labor Production.....	Joseph D. Keenan.
Vice Chairman for Manpower Requirements.....	Clinton S. Golden.
Operations Vice Chairman.....	Harold Boeschstein.
Vice Chairman for Metals and Minerals.....	R. C. Allen.
Executive Assistant.....	Albert Butler.
Deputy Vice Chairman for Production.....	James Douglas.
Assistant Deputy Vice Chairman for Production.....	Roland D. Parks.
Mineral Resources Operating Com- mittee:	
Chairman.....	James Douglas.
Alternate Chairman.....	Roland D. Parks.
Bureau of Mines.....	R. S. Dean.
Foreign Economic Administra- tion.....	Alan M. Bateman.
Reconstruction Finance Cor- poration.....	Simon D. Strauss.
Office of Production Research and Development.....	C. K. Leith.
Minerals and Metals Advisory Com- mittee:	
Chairman.....	James Douglas.
Alternate Chairman.....	Roland D. Parks.
War Department.....	Lt. Col. John A. Church.
Navy Department.....	Comdr. J. W. Palen.
Bureau of Mines.....	R. S. Dean.
Metals Reserve Company.....	Simon D. Strauss.
Geological Survey.....	Donnel F. Hewett.
Foreign Economic Administra- tion.....	Alan M. Bateman.
Bureau of Foreign and Domes- tic Commerce.....	Walter Janssen.
Office of Civilian Requirements.....	Carroll Burton.
Office of Production Research and Development.....	C. K. Leith.
State Department.....	Charles E. Gamper.
Labor Production Division.....	Clinton Golden.
Stock-piling and Transporta- tion Division.....	Morton M. Banks.
Premium Price Quota Committee	
Chairman.....	Roland D. Parks.
Secretary.....	Landon F. Strobel.
War Production Board, Tin- Lead-Zinc Division.....	C. A. Wright.
War Production Board, Tin- Lead-Zinc Division.....	Edgar E. Barker.
War Production Board, Copper Division.....	Edward J. Craig.
Office of Price Administration.....	Jesse L. Maury.
Office of Price Administration.....	J. J. Beeson.
Office of Price Administration.....	C. O. Mittendorf.
Aluminum and Magnesium Division, Director.....	Nigel H. Bell.
Deputy Director.....	T. E. Covel.

WAR PRODUCTION BOARD—Continued

*Staff—Continued*Vice Chairman for Metals and Minerals—
Continued.

Copper Division, Director.....	Michael Schwarz.
Assistant Director.....	Frank H. Hayes.
Assistant Director.....	John J. Hines, Jr.
Steel Division, Director.....	William B. Todd.
Deputy Director.....	H. M. Francis.
Assistant Director for Manpower...	Philip J. Clowes, Acting.
Assistant Director for Production...	R. F. Sentner.
Assistant Director for Raw Materials and Facilities.	H. J. French.
Plant Facilities Branch, Chief...	H. W. Bryant.
Metallurgical Branch, Chief...	E. J. Hergenroether.
Raw Materials Branch, Chief...	Alex Miller.
Assistant Director for Ferro-Alloys and Alloy Steels.	Louis E. Creighton.
Cork, Asbestos and Fibrous Glass Division, Director.	William T. Meloy.
Deputy Director.....	J. E. Cole, Acting.
Mining Division, Director.....	Arthur S. Knolzen.
Deputy Director.....	Marcellus H. Stow.
Miscellaneous Minerals Division, Director.	F. G. Rockwell.
Deputy Director.....	Frank F. Watts.
Tin-Lead-Zinc Division, Director.....	Erwin Vogelsang.
Deputy Director.....	S. K. Butterworth.
Deputy Director.....	Myron Trilsch.

Office of Price Administration.—During the year the Office followed the same general policies in the pricing of minerals, and no change was made in the standards governing price increases. Moderate increases were granted in the maximum prices for solid fuels and for certain nonmetallic minerals. No price increases were authorized for any of the basic metals, although increases were permitted for some steel products. Throughout 1944 the premium price plan for copper, lead, and zinc remained in effect.

Chester Bowles continued as Administrator and James F. Brownlee as Deputy Administrator for Price. As of May 15, 1945, the following units and executives of the Price Department were administering prices for minerals:

Industrial Materials Price Division, Director.....	John S. Clement.
Building Materials Branch, Price Executive....	Karl Mathiasen.
Iron and Steel Branch, Price Executive.....	Warren M. Huff.
Nonferrous Metals Branch, Price Executive....	Karl L. Anderson.
Metal Mining Analysis Office, Director.....	Jesse L. Maury.
Industrial Manufacturing Price Division, Director.	John S. Clement.
Rubber, Chemicals and Drugs Branch, Price Executive.	Lester V. Chandler.
Fuel Price Division, Director.....	Sumner T. Pike.
Associate Director.....	Orville Judd.
Petroleum Branch, Price Executive.....	Eugene D. Uman.
Solid Fuels Branch, Price Executive.....	J. H. Reppert.

Petroleum Administration for War.—The organization and functions of this war agency were essentially the same in 1944 as in 1943, although some administrative adjustments were made to meet problems posed by the changing conditions of war.

The delegation of authority to the five district Directors to rule on questions of local significance was continued and broadened in scope in 1944. The central office in Washington was thus relieved of much

detail, and expeditious handling of matters of direct concern to oil and gas operators was possible.

As the availability of materials improved during the year, controls over the spacing of wells and minor construction projects connected with production, refining, transportation, and marketing were relaxed in a series of orders. Under this program, a large percentage of the projects that formerly required specific authorization became eligible for automatic approval within the limits prescribed. These actions effected a substantial reduction in the negotiations, paper work, and attendant delays and minor irritations inherent in the regulation of routine activities of a highly complex industry.

To aid the petroleum industry in maintaining a sufficient force for the required rate of operations during periods of critical manpower shortage, the Petroleum Administration became the claimant agency for deferment from the draft of the industry's essential workers 18 to 26 years of age. Manpower counselors were attached to three of the five district offices (Chicago, Houston, and Los Angeles) to assist in keeping industry informed concerning regulations and trends in manpower programs and planning as seen from the national and regional levels and to suggest area and regional programs designed to maintain or increase, as necessary, manpower in particular branches of the industry.

The great construction program initiated by the Petroleum Administration in 1941 to equip refineries in the United States for the manufacture of unprecedented quantities of 100-octane aviation gasoline was substantially completed in 1944. Similar construction at refineries in foreign countries was approaching completion in early 1945.

PAW directs world-wide petroleum-supply operations of the United Nations in keeping with a World Supply Program developed in collaboration with the military and shipping authorities of this Government and the British and designed to assure the most effective utilization of all available petroleum production, refining, and transportation facilities. The importance of this function has grown with the prospect of utilizing more oil from foreign sources as shipping lanes are cleared of the enemy and the carrying capacity of the tanker fleet increases. Organization machinery for interagency coordination with respect to foreign petroleum problems is provided also by the Foreign Petroleum Committee, and other Government committees that have been created to deal with special aspects, such as materials procurement for foreign petroleum operations, and petroleum supply programs for the liberated areas.

The principal officials of PAW, on July 1, 1945, follow:

Administrator.....	Harold L. Ickes.
Deputy Administrator.....	Ralph K. Davies.
Executive Assistant to Deputy Administrator.	H. Chandler Ide.
Chief Counsel.....	R. E. Hardwicke.
Production Division.....	J. R. McWilliams, Director.
Natural Gas and Natural Gasoline Division.	J. E. Pew, Director.
Supply and Transportation Division....	G. A. Wilson, Director.
Refining Division.....	A. P. Frame, Director.
Distribution and Marketing Division....	W. Hochuli, Director.
Foreign Production Division.....	W. B. Heroy, Director.
Foreign Refining Division.....	O. S. Snodgrass, Director.

Foreign Supply and Distribution Division	R. F. Hawkins, Director.
Materials Division	E. E. Robbins, Director.
Facility Security Division	W. K. McCoy, Director.
Research Division	E. B. Swanson, Director.
Public Relations Division	Ludwig Caminita, Jr., Director.
Program Division	W. H. Page, Director.
Executive Officer	W. H. Newman.
Labor-Manpower Counselor	G. E. Dewey.

Solid Fuels Administration for War.—The origin and functions of this agency were described briefly in *Minerals Yearbook*, 1943.

Harold L. Ickes continued as Administrator and Charles J. Potter as Deputy Administrator during the past year. Various actions taken by this agency during 1944 are presented in the chapters of this volume covering coal and coke.

The Coal Mines Administration, set up in July 1943 to supervise the operation of coal mines in Government possession, was liquidated on September 15, 1944, and its responsibilities were turned over to the Solid Fuels Administration.

Two bituminous-coal mines taken over by the Coal Mines Administration continued in Government possession under the Solid Fuels Administration. In addition, by separate Executive orders, the properties of one anthracite-mining company and 73 bituminous mines were taken over in the summer and fall of 1944 as a result of labor disputes. All these mines, except the original 2, were returned to private ownership in the winter of 1944-45. In April and May 1945, under Executive Orders 9536 and 9548, the Solid Fuels Administration took over 272 bituminous-coal mines, 2 Virginia anthracite mines, and the properties of 363 anthracite companies that were strike-bound as a result of wage disputes.

In May 1944 the Economics and Statistics Division of the Solid Fuels Administration for War was transferred to the Bureau of Mines, where it was consolidated with the Coal Economics Division of the Economics and Statistics Branch.

As of June 1, 1945, the organization of the Solid Fuels Administration for War was as follows:

Administrator	Harold L. Ickes.
Deputy Administrator	Charles J. Potter.
Assistant Deputy Administrator for Prices, Manpower and Administration	Dan H. Wheeler.
Assistant Deputy Administrator for Coke	Harlen M. Chapman.
Assistant Deputy Administrator for Transportation	Clark M. Groninger.
Assistant to the Deputy Administrator	Charles H. Hayes.
Head Administrative Officer	John E. MacDonald.
General Counsel	Jesse B. Messitte.
Chief, Anthracite Distribution Division	Thomas G. Valteau.
Chief, Bituminous Distribution Division	William F. Hahman.
Chief, Compliance Division	Thomas J. O'Brien.
Chief, Conservation and Information Division	Leonard W. Mosby.
Personnel Officer	George C. Dickens.
Chief, Budget and Administrative Services Division	Waldron E. Leonard.
Chief, Field Office Division	Newton O. Wood, Jr.

Advisory bodies providing counsel to the Solid Fuels Administration include the following:

Solid Fuels Advisory War Council.
National Anthracite Distribution Committee.
Regional Anthracite Distribution Committee.

Producer Advisory Boards for the 22 bituminous coal production districts.
 Lake Dock and Tidewater Dock Advisory Committees.
 National Advisory Coke Committee.
 National Committee on Local Distribution.
 Area Advisory Committees on Local Distribution.
 Community Committees on Emergency Distribution.

Foreign Economic Administration.—This agency, successor to the Board of Economic Warfare and Office of Economic Warfare, which was created within the Office of Emergency Management by Executive Order 9380 issued on September 25, 1943, directs the foreign economic activities of the United States Government, including the procurement of metals and minerals from abroad. Leo J. Crowley is the Administrator.

The Agency operates through two major bureaus—a Bureau of Supplies, of which Sidney H. Scheuer is Executive Director, and a Bureau of Areas, directed by Arthur Paul. Foreign procurement of commodities is carried on in a Foreign Procurement and Development Branch, of which Arthur Z. Gardiner is Director.

The development and procurement of foreign minerals are handled by the FEA, and purchases are made in the name of its corporate fiscal agent, United States Commercial Company, a United States Government-owned corporation. This has been true since September 1943, when the foreign procurement functions of the Metals Reserve Company were transferred to United States Commercial Company. In general, Metals Reserve Company, an RFC subsidiary, purchases foreign metals and minerals from United States Commercial Company ex-dock at United States ports of entry or f. o. b. cars at border points and undertakes the domestic sale and distribution of such materials. This transfer signaled completion of the withdrawal of the RFC from the foreign minerals procurement field, with the exception of continued responsibility for some large development projects, financed by the Defense Plant Corporation and the Metals Reserve Company.

With this exception, actual operations in the foreign minerals procurement field are conducted by the Metals and Minerals Divisions of the Foreign Procurement and Development Branch in the FEA. Key officials on the technical staff of these two Divisions and of the Associated Technical Services Division were as follows on July 1, 1945:

Associate Director of Foreign Procurement and Development Branch in charge of Metals and Minerals—Alan M. Bateman

Metals Division, Chief.....	Mahlon M. Miller.
Assistant Chief.....	Horace J. Fraser.
Copper Section, Chief.....	William C. Schmidt.
Zinc-Lead Section, Chief.....	F. R. McIntosh.
Tin, Mercury, Antimony, Bauxite Section, Chief.....	Clarence E. Peterson.
Ferro-Alloy Section, Chief.....	Cayford Burrell.
Scrap Metals Section, Chief.....	Benjamin Schwartz.
Minerals Division, Chief.....	Hugh E. McKinstry.
Mica-Graphite Section, Chief.....	Richard H. Vail.
Quartz and Abrasives Section, Chief.....	Carl Tolman.
Alloy and Rare Minerals Section, Chief.....	Robert W. Bridgeman.
Engineering Analysis and Contract Control Section, Chief.....	Robert K. Warner.
Service and Supply Section, Chief.....	Marshall Walker.

Reconstruction Finance Corporation.—This agency has had a tremendous part in carrying out the defense and war programs on the industrial front, including the construction and management of mineral processing plants and the procurement of strategic and critical minerals. The Corporation was created by act of Congress approved January 22, 1932, to extend financial assistance to commerce, agriculture, and industry by direct loans to banks and other credit agencies as a means of combating the depression. Although its powers and functions for war purposes have been broadened greatly by numerous Executive orders and amendments to the original enabling act, the Board acts largely under directives from and at the request of the Army and Navy and the other war agencies.

Under the President's Reorganization Plan 1, dated April 25, 1939, the Reconstruction Finance Corporation and other credit organizations of the Government were placed within a newly created Federal Loan Agency. Jesse H. Jones, who had served as Chairman of the Corporation for many years, became Administrator of the loan agency, which position he continued to occupy after he was appointed Secretary of Commerce in 1940. On February 24, 1942, by Executive order, the Reconstruction Finance Corporation and certain other units of the Loan Agency were transferred to the United States Department of Commerce.

Following the retirement of Jones from Government service in January 1945 Congress, by an act approved February 24, 1945, reestablished the Federal Loan Agency as an independent unit of government, to which were transferred the Reconstruction Finance Corporation and other loan activities placed in the United States Department of Commerce on February 24, 1942. Fred M. Vinson was appointed Administrator of the new agency and was succeeded by John W. Snyder in April. The post was left vacant following Snyder's transfer to the Office of War Mobilization and Reconversion in July. Charles B. Henderson is Chairman of the Board of Directors of the Reconstruction Finance Corporation.

To carry out its war responsibilities the Reconstruction Finance Corporation created several subsidiaries, some of which, by act of Congress, effective July 1, 1945, were consolidated into the Reconstruction Finance Corporation itself. Commenting on this merger, Federal Loan Administrator Snyder stated that it was an important step toward simplification of the Corporation which was possible "now that the Nation had successfully constructed its Arsenal of Democracy." He also stated that, as of January 1945, authorizations by these subsidiary corporations, together with RFC direct commitments for war purposes of approximately \$2,600,000,000 have amounted to \$32,300,000,000. Disbursements have exceeded \$18,000,000,000, including \$1,400,000,000 for direct subsidy payments to increase or maintain production of strategic or critical materials. The latter figure does not include losses arising from the purchase and sale of such materials. Repayments of loans and advances and other receipts, such as rents, part payments on plants and equipment, and proceeds from sales of materials have totaled \$9,100,000,000.

METALS RESERVE COMPANY

A very large part of the war procurement of strategic and critical metals and minerals has been conducted by this agency. Total commitments for this purpose through 1944 aggregated \$5,174,000,000, of which \$2,150,000,000 has been disbursed and \$2,149,000,000 canceled or assigned to industry or the Foreign Economic Administration. Sales of materials, principally to war industries, have amounted to \$1,813,000,000. Stock piles on hand cost \$538,600,000; in addition, the Company has large assets such as advances to contractors and other receivables, and mining equipment and supplies in the amount of \$67,800,000.

Charles B. Henderson was President of the Company at the time of the merger. Harvey J. Gunderson was Executive Vice President, having succeeded H. Dewitt Smith, who resigned in November 1944. Following the merger Gunderson was named Executive Director of an Office of Metals Reserve. Simon D. Strauss and DeWitt C. Schieck, former Vice Presidents, were named Deputy Directors.

DEFENSE PLANT CORPORATION

Most of the war expansion of industrial capacity and plant for the production of munitions and strategic and critical materials has been conducted through this agency. Total commitments on January 1, 1945, for war plants, facilities, and machine tools were \$10,704,935,000, of which \$757,656,000 had been canceled and \$7,177,700,000 disbursed. These commitments included 920 complete, integrated plants, wholly owned by the Corporation, involving \$6,055,000,000, and expansions at 122 existing privately owned plants, involving \$740,000,000. These expansions are wholly owned by the Corporation and are located on land owned by it or held under long-term lease. Commitments to produce critical and strategic materials in foreign countries totaled \$42,714,850.

At the time of the merger Sam H. Husbands was President of the Corporation and Hans A. Klagsbrunn Executive Vice President. After the merger the latter was named Executive Director of an Office of Defense Plant.

DEFENSE SUPPLIES CORPORATION

Although this agency has been concerned chiefly with products other than minerals, it has had some important functions related to the mineral industries. Its operations have included the purchase of strategic and critical materials, the payment of extraordinary transportation costs in oil, coal, and sugar, and various other activities such as the making of loans and the payment of subsidies in connection with the purchase of materials. Disbursements for such purposes as of January 1, 1945, were \$5,200,000,000. Receipts from the sale of materials, repayment of loans, etc., amounted to \$3,600,000,000. Total expenditures authorized by the Corporation aggregated \$10,350,000,000, of which \$800,000,000 had been canceled or assumed by private industry.

Stuart K. Barnes, former Vice President of the Corporation, was appointed Executive Director of the Office of Defense Supplies after the merger.

STATISTICAL SUMMARY OF MINERAL PRODUCTION

(GENERAL UNITED STATES SUMMARY AND DETAILED PRODUCTION BY STATES)

By MARTHA B. CLARK AND MARIAN E. MEYER

SUMMARY OUTLINE

	Page		Page
Production.....	27	General tables.....	29
Unit of measurement.....	27	State tables.....	41
Elimination of duplication.....	27		

INTRODUCTION

This report continues the series of annual statistical summaries published in previous years as chapters of Mineral Resources and Minerals Yearbook.

In order to meet the need of industry and the States for up-to-date statistics on State production of minerals, State summaries are presented for the current year. Because of the early date of publication, the fuel figures for 1944 are estimates subject to revision; it is believed, however, that the data shown represent a high order of accuracy.

UNIT OF MEASUREMENT

The unit of measurement used by the Bureau of Mines for each mineral product in reports on the mineral resources is that common to the industry concerned, and the variation in these units makes it impracticable, if not impossible, directly to combine and compare the different minerals except as to value. Although most of the products are measured by weight, some are measured by volume and some by number of "pieces," etc.; for some no total quantity figures are available.

ELIMINATION OF DUPLICATION

In the totals for the United States, shown in the following "general" tables, duplication has been eliminated wherever practicable, and in the State totals given in the State tables virtually all duplication has been eliminated. For instance, in both general and State tables the output of coke is shown but its value is not included in the totals, as the value of the coal used in its manufacture enters into the value of the coal production which is included in the totals. For asphalt, both native and oil are shown in the general tables, but the value of the oil asphalt is excluded from the totals as it duplicates that of the petroleum from which it is manufactured. For the clay industries, no figures have been available for total clay produced. For years before 1936, the total value of clay products is included in both general and State totals as representing the first marketable form of the

greater part of the clay produced; the quantity and value of the clay mined and sold in the raw state by miners to users of clay are shown separately also, but the value is not included in the totals as it is duplicated largely in that for clay products. For years beginning with 1936, as the Bureau of Mines believes that a closer approach to the value of domestic clay in its first marketable form results from the inclusion of the value of clay sold or shipped by producers and of clay products other than pottery and refractories, the United States and State totals include such values for the clay industries. This change in practice should be borne in mind when comparing the values beginning 1936 with those for earlier years.

United States totals.—In the general tables both iron ore and pig iron are shown, but the value of the pig iron rather than the iron ore is included in the United States totals, as that is considered the better means of presenting the statistics for iron in its first marketable form. For gold, silver, copper, lead, and zinc the value of "smelter output" is included in the general totals, and to account more fully for the value of the ores treated these smelter figures are supplemented by the value of the byproduct sulfuric acid. The value of pigments (white lead, red lead, lithopone, litharge, and orange mineral) manufactured from metals is not included in the general tables, as the base from which they are made is included in the output of lead or zinc, whereas the value of sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide is included, as these are made in large part direct from the ores and do not enter into the lead or zinc totals, which represent smelter output.

State totals.—In the State tables also iron ore and pig iron are both shown. As blast-furnace products cannot be traced to the States in which the ore is mined, the value of the ore is used in the State totals. For ores of gold, silver, copper, lead, and zinc no values are shown, and in fact none are recorded; instead, for each of these metals the recoverable content of the ores is used as the basis of valuation. The value of the zinc and lead pigments is not included in the State total, as the recoverable zinc and lead content of the ores from which the products were made is included under zinc or lead. The value of the sulfuric acid produced as a byproduct of copper, lead, and zinc smelting and zinc roasting is not included in the State total, as tracing this product back to the State producing the ore has not been possible.

GENERAL TABLES
Mineral products of the United States, 1942-44

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value

Mineral products of the United States, 1942-44—Continued

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value
NONMETALLIC—continued						
Vermiculite.....	57,848	\$319,931	46,645	\$471,595	54,116	\$541,744
Other nonmetallic ^a		4,265,893		4,770,156		4,511,391
Total value of nonmetallic products (approximate).....		5,212,400,000		5,583,000,000		6,112,000,000
SUMMARY						
Total value:						
Metallic.....		2,363,900,000		2,488,000,000		2,340,000,000
Nonmetallic:						
Fuels.....		4,103,400,000		4,608,300,000		5,212,000,000
Other.....		1,109,000,000		974,700,000		900,000,000
Grand total approximate value of mineral products.....		7,576,300,000		8,071,000,000		8,452,000,000

^a In this general statement certain of the figures represent shipments rather than quantity mined, and some of the figures for 1944 are subject to revision. For details see following chapters of this volume.

^b Figures represent antimonial lead produced at primary refineries from both domestic and foreign primary and secondary sources; no figures for value of antimonial lead available. Estimate of value of primary antimony and lead contents of antimonial lead from domestic sources included in total value of metallic products.

^c Largely from foreign ore; value not included in total value.

^d 1942-43: As shipped; 1944: Dried-bauxite equivalent.

^e Product from domestic ores only.

^f Value does not include premiums paid to miners by the Government. Total over-riding payments for copper, lead, and zinc amounted to approximately \$26,000,000 in 1942, \$73,000,000 in 1943, and \$89,000,000 in 1944.

^g According to Bureau of the Mint. Valued at \$35 per ounce.

^h Value not included in total value.

ⁱ Figures not available.

^j Figures showing values not available.

^k Figures included in total value of metallic products; Bureau of Mines not at liberty to publish figures.

^l According to Bureau of the Mint.

^m Includes value of following products. Figures are shown wherever Bureau of Mines is at liberty to publish them.

1943 and 1944: Bismuth, cobalt, germanium, indium, radium, thallium, and zircon.

1943 and 1944: Bismuth, cobalt, germanium, indium, thallium, and zircon.

ⁿ Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.

^o Includes brown coal and lignite, and anthracite mined elsewhere than in Pennsylvania.

^p Value included in total value of nonmetallic products; Bureau of Mines not at liberty to publish figures.

^q No canvass. Estimate of value included in total value of nonmetallic products.

^r Figures cover fiscal year ended June 30 of year stated.

^s Sublimed blue lead, sublimed white lead, leaded zinc oxide, and zinc oxide.

^t Equivalent as K₂O.

^u Figures for soapstone used as dimension stone included in figures for stone.

^v From copper, lead and zinc smelters and zinc roasters.

^w Includes value of following products. Figures are shown wherever Bureau of Mines is at liberty to publish them.

1942: Andalusite, crude apatite, natural sulfonated bitumen, dumortierite, flint lining for tube mills (2,576 short tons, \$49,967), pebbles for grinding (15,437 short tons, \$245,794), silica sand and sandstone (ground) (527,886 short tons, \$3,646,643), strontium minerals (4,041 short tons, \$55,529), sulfur ore (1,590 long tons, \$16,000), and industrial topaz.

1943: Andalusite, crude apatite, natural sulfonated bitumen, calcite (Iceland spar), corundum, dumortierite, flint lining for tube mills (2,385 short tons, \$46,071), pebbles for grinding (9,924 short tons, \$157,778), quartz crystal (5,968 pounds, \$25,598), silica sand and sandstone (ground) (541,350 short tons, \$3,937,452), strontium minerals (7,566 short tons, \$114,526), sulfur ore (2,572 long tons, \$26,215), industrial topaz, and wollastonite.

1944: Andalusite, crude apatite, natural sulfonated bitumen, calcite (Iceland spar) (5,748 pounds, \$57,480), corundum, dumortierite, flint lining for tube mills (2,063 short tons, \$38,839), pebbles for grinding (8,012 short tons, \$172,418), quartz crystal (3,934 pounds, \$23,769), silica sand and sandstone (ground) (538,606 short tons, \$3,989,951), strontium minerals (3,005 short tons, \$48,163), sulfur ore (1,639 long tons, \$8,950), industrial topaz, and wollastonite.

Value of mineral products of the United States, 1880-1944¹

Year	Metallic	Nonmetallic			Grand total

¹ Figures for earlier years not available.² Coal, natural gas, natural gasoline and allied products, petroleum.³ Subject to revision.

The sum of the following State totals does not reach the total for the United States given in the preceding table partly because figures for certain of the products included in the United States total are not available by States of origin. This fact is brought out in the opening text of this chapter and in the second table following.

In addition, there are many factors (the more important discussed in the opening text) that account for the disagreement between the sum of the State totals and the grand total for the United States, by products. Chief among these are: (1) The use of iron ore values in State totals and pig iron values in United States total; (2) the use of mine figures for gold, silver, copper, lead, and zinc in the State totals and mint and smelter figures (supplemented by the value of byproduct sulfuric acid from copper, lead, and zinc smelting and zinc roasting and the value of zinc and lead pigments made in large part direct from ores) in the United States total; and (3) the inclusion of estimates in the United States total for a few products for which no canvass has been conducted for many years and for which no estimate by States is made.

Many other less important differences are involved, but both State and United States totals are as complete and definite as seems possible with the data available. The practice is consistent from year to year, and it is believed that the reader can determine readily just what minerals are covered by the total concerned.

In every table each mineral produced is listed, and all figures are shown except those that the Bureau of Mines is not at liberty to publish.

Value of mineral products of the United States, 1940-44, and total, 1911-44, by States

State	1941-44 ¹					Percent of total for United States

84	Pebbles for grinding.....	Rank same as for quantity.
81	Petroleum.....	Do.
32	Phosphate rock.....	Florida, Tennessee, Idaho, Montana.
61	Platinum metals.....	Rank same as for quantity.
27	Potassium salts.....	Do.
66	Pumice.....	Do.
53	Pyrites.....	Do.
97	Quartz crystal.....	New Mexico, Kansas, California, Nebraska.
22	Salt.....	Tennessee, Virginia, California, New York.
12	Sand and gravel.....	Arkansas, California, North Carolina, Virginia.
59	Selenium.....	Michigan, New York, Kansas, Ohio.
75	Silica (quartz).....	California, Ohio, Illinois, Pennsylvania.
49	Silica sand and sandstone (ground).....	Not separable by States.
25	Silver.....	Washington, California, North Carolina, Wisconsin.
43	Slate.....	Illinois, Ohio, New Jersey, Pennsylvania.
47	Sodium salts (carbonates and sulfates) (natural).....	Rank same as for quantity.
11	Stone.....	Pennsylvania, Vermont, New York, Maine.
86	Strontium minerals.....	Rank same as for quantity.
21	Sulfur.....	Do.
34	Sulfuric acid from copper, lead, and zinc smelters and zinc roasters.....	Pennsylvania, Illinois, Tennessee, Indiana.
96	Sulfur ore.....	Rank same as for quantity.
42	Talc, pyrophyllite, and ground soapstone.....	New York, California, Vermont, North Carolina.
95	Tantalum and columbium ores.....	New Mexico, Colorado, South Dakota, North Carolina.
88	Tenarum.....	Not separable by States.
91	Thallium.....	Do.
103	Tin.....	Rank same as for quantity.
100	Tinanium concentrates.....	Do.
50	Uranite.....	Do.
67	Uranium.....	Do.
98	Uranium (industrial).....	Do.
80	Vanadium.....	Do.
32	Vanadium ore.....	Do.
51	Vermiculite.....	Do.
72	Wollastonite.....	Do.
105	Zinc.....	Do.
14	Zinc.....	Oklahoma, Idaho, New Jersey, New Mexico.
102	Zircon.....	Rank same as for quantity.

¹ Rank of States in metal production (except aluminum, ferro-alloys, and pig iron) arranged according to mine reports, not smelter output. Compilation of rank for 1944 not yet available.

² Separate figures for antimonial lead from primary sources not available.

2 Separate figures for anthracite and bituminous coal from primary sources not available.
 3 No canvass for 1943.
 4 Value not available.
 5 Exclusive of soapstone used as dimension stone (all from Virginia), which is included in figures for stone.

³ No canvass for 1943.

States and their principal mineral products in 1943¹

State	Rank	Percent of total value for United States	Principal mineral products in order of value
Alabama.....	16	1.55	Coal, iron ore, cement, stone.
Alaska.....	38	.14	Gold, sand and gravel, coal, platinum metals.
Arizona.....	14	1.89	Copper, gold, zinc, silver.
Arkansas.....	22	1.23	Bauxite, petroleum, coal, natural gas.
California.....	3	8.87	Petroleum, natural gas, natural gasoline, cement.
Colorado.....	18	1.34	Molybdenum, coal, zinc, gold.
Connecticut.....	43	.07	Magnesium, stone, clay products, sand and gravel.
Delaware.....	49	.01	Clay products, sand and gravel, stone, raw clay.
District of Columbia.....	50	(²)	Clay products.
Florida.....	30	.38	Phosphate rock, stone, cement, sand and gravel.
Georgia.....	34	.32	Raw clay, stone, cement, clay products.
Idaho.....	26	.87	Zinc, lead, silver, tungsten ore.
Illinois.....	5	4.88	Coal, petroleum, stone, sand and gravel.
Indiana.....	21	1.27	Coal, cement, petroleum, stone.
Iowa.....	31	.37	Coal, cement, stone, clay products.
Kansas.....	9	3.34	Petroleum, natural gas, zinc, coal.
Kentucky.....	8	3.59	Coal, natural gas, petroleum, stone.
Louisiana.....	6	4.08	Petroleum, natural gas, natural gasoline, sulfur.
Maine.....	46	.04	Sand and gravel, cement, stone, slate.
Maryland.....	36	.26	Coal, sand and gravel, cement, stone.
Massachusetts.....	42	.08	Stone, sand and gravel, lime, clay products.
Michigan.....	13	2.38	Iron ore, petroleum, salt, natural gas.
Minnesota.....	11	2.60	Iron ore, manganese ore, sand and gravel, stone.
Mississippi.....	33	.32	Petroleum, sand and gravel, clay products, raw clay.
Missouri.....	23	1.09	Lead, coal, cement, zinc.
Montana.....	17	1.39	Copper, petroleum, coal, zinc.
Nebraska.....	40	.10	Cement, sand and gravel, stone, petroleum.
Nevada.....	27	.86	Copper, magnesium, gold, tungsten ore.
New Hampshire.....	47	.02	Mica, feldspar, clay products, stone.
New Jersey.....	29	.57	Zinc, sand and gravel, clay products, stone.
New Mexico.....	15	1.88	Petroleum, potassium salts, copper, natural gas.
New York.....	19	1.34	Petroleum, iron ore, zinc, salt.
North Carolina.....	32	.34	Bromine, stone, clay products, mica.
North Dakota.....	45	.07	Coal, sand and gravel, natural gas, clay products.
Ohio.....	10	2.87	Coal, natural gas, stone, clay products.
Oklahoma.....	7	3.86	Petroleum, natural gas, zinc, natural gasoline.
Oregon.....	37	.19	Sand and gravel, cement, stone, mercury.
Pennsylvania.....	2	13.47	Coal, petroleum, natural gas, cement.
Rhode Island.....	48	.01	Stone, sand and gravel, graphite, clay products.
South Carolina.....	44	.07	Stone, clay products, raw clay, sand and gravel.
South Dakota.....	39	.13	Gold, stone, raw clay, cement.
Tennessee.....	25	.98	Coal, stone, zinc, cement.
Texas.....	1	16.72	Petroleum, natural gas, natural gasoline, sulfur.
Utah.....	12	2.49	Copper, coal, gold, zinc.
Vermont.....	41	.10	Stone, slate, talc, lime.
Virginia.....	20	1.30	Coal, stone, sand and gravel, zinc.
Washington.....	28	.57	Cement, sand and gravel, coal, magnesite.
West Virginia.....	4	8.55	Coal, natural gas, petroleum, natural gasoline.
Wisconsin.....	35	.29	Stone, iron ore, zinc, sand and gravel.
Wyoming.....	24	1.07	Petroleum, coal, natural gas, iron ore.

¹ In this table iron ore, not pig iron, is taken as the basis of iron valuation, and for other metals mine production (recoverable content of metals) is the basis. Compilation of rank for 1944 not yet available.

² Less than 0.01 percent.

Prices of gold, silver, copper, lead, and zinc, 1932-44¹

Year	Gold ²	Silver ³	Copper ⁴	Lead ⁴	Zinc ⁴
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1932.....	\$20.67+	\$0.282	\$0.063	\$0.030	\$0.030
1933.....	25.56	.350	.064	.037	.042
1934.....	34.95	.646+	.080	.037	.043
1935.....	35.00	.71875	.083	.040	.044
1936.....	35.00	.7745	.092	.046	.050
1937.....	35.00	.7735	.121	.059	.065
1938.....	35.00	.646+	.098	.046	.048
1939.....	35.00	.7678+	.104	.047	.052
1940.....	35.00	.711+	.113	.050	.063
1941.....	35.00	.711+	.118	.057	.075
1942.....	35.00	.711+	.121	.067	.093
1943.....	35.00	.711+	.130	.075	.108
1944.....	35.00	.711+	.135	.080	.114

¹ Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ per fine ounce. For table of prices for silver, copper, lead, and zinc from 1850 to 1931, by years, see Mineral Resources, 1931, pt. 1, p. A115.

² 1932: Legal coinage value; 1933-34: Yearly average weighted Government price; 1935-44: Price under authority of Gold Reserve Act of January 31, 1934.

³ 1932-33: Average New York price for bar silver; 1934 and 1938-44: Treasury buying price for newly mined silver; 1935-37: Yearly average weighted Treasury buying price for newly mined silver.

⁴ Yearly average weighted price of all grades of primary metal sold by producers. Beginning 1942, price includes premiums paid to miners by the Government.

² \$20.671835.

³ \$0.646464.

⁴ \$0.678787.

⁵ \$0.71111111.

Zinc.....	55, 574	1, 392, 994	56, 944	12, 239, 994	65, 703	14, 324, 284
Miscellaneous ¹		2, 902, 880		2, 601, 179		3, 937, 901
Total value, eliminating duplications.....		201, 454, 022		220, 413, 000		219, 678, 000

¹ Exclusive of natural cement, value of which is included under "Miscellaneous."
² Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.
³ Value included under "Miscellaneous."
⁴ Figures cover fiscal year ended June 30 of year stated.

⁵ Value not included in total value for State.
⁶ No canvass.
⁷ Not valued as ore; value of recoverable metal content included under the metals.
⁸ Includes minerals indicated by "1" and "9" above.

Mineral products of the United States, 1943-44, by States—Continued

MAINE

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value
Beryllium ore.....	45	(1)	2	\$169	2	\$267
Cement.....	(1)	(1)	(1)	(1)	(1)	(1)
Clay products (other than pottery and refractories).....	8,335	\$300,000	6,748	\$120,000	8,011	(1)
Feldspar (crude).....	(1)	\$3,143	(1)	\$41,652	(1)	\$47,892
Gems and precious stones.....	(1)	(1)	(1)	(1)	(1)	(1)
Lime.....	103	4,328	(1)	(1)	(1)	(1)
Lithium minerals.....	(1)	(1)	(1)	(1)	(1)	(1)
Mica:						
Scrap.....	(1)	(1)	240	5,862	64	1,602
Sheet.....	3,122	1,946	51,576	63,845	28,008	40,803
Mineral waters.....	(1)	(1)	(1)	(1)	(1)	(1)
Peat.....	3,832	110,478	1,871	60,033	2,276	80,732
Sand and gravel.....	2,249,254	800,147	1,603,324	733,803	1,940,066	710,047
Silica (quartz).....	364	922	140	840	88	203
Slate.....	480,391	480,391	201,450	(1)	125,840	(1)
Stone.....	419,610	4,556,655	201,450	409,780	125,840	332,736
Miscellaneous ¹	(1)	1,306,044	(1)	1,284,761	125,840	332,131
Total value, eliminating duplications.....		3,614,054		2,720,000		2,146,000

¹ Value included under "Miscellaneous."² Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.³ No canvass.⁴ Exclusive of unclassified stone in 1942 and of basalt in 1944, value for which is included under "Miscellaneous."⁵ Includes minerals indicated by "1" and "a" above.

MARYLAND

Product	1942		1943		1944

Total value, eliminating duplications.....

* No census.
 * Exclusive of dimension limestone, value for which is included under "Miscellaneous."
 * Estimated by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.
 * Value not included in total value for State.

 6 Includes minerals indicated by "1," above.

NEW HAMPSHIRE

	16	\$1,286	42	\$6,305	(1)	(1)
Beryllium ore.....	short tons	230,000		200,000		(1)
Clay products (other than pottery and refractories).....	long tons	241,990	(1)	(1)	(1)	(1)
Feldspar (crude).....				(1)		(1)
Gems and precious stones.....						(1)
Mica:						
Scrap.....	303	7,224	1,148	28,643	2,339	\$55,851
Sheet.....	342,939	57,995	700,543	583,543	323,636	617,172
Mineral waters.....			(1)	(1)	(1)	(1)
Peat.....	(1)		80	1,705	(1)	(1)
Sand and gravel.....	1,287,394	159,058	611,582	126,325	838,668	120,943
Scythstones.....	do.	(1)	(1)	(1)	(1)	(1)
Stone.....	237,090	440,714	70,910	171,371	910	48,000
Miscellaneous.....		12,907		231,666		323,774
Total value, eliminating duplications.....		1,211,184		1,350,000		1,166,000

1 Value included under "Miscellaneous."
 2 Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.
 3 No canvas.
 4 Includes minerals indicated by "i" above.

Mineral products of the United States, 1942-44, by States—Continued

NEW YORK

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value
Aluminum.....	(1) (2)	(1) (2)	(1) (2)	(1) (2)	(1) (2)	(1) (2)
Cement.....	11,027, 118	\$16,030,995	5,914,660	\$8,765,665	3,411,605	\$6,839,676
Clay.....	(1)	6,000,000	(1)	3,000,000	(1)	1,500,000
Products (other than pottery and refractories).....	5,180,384	237,660,727	5,347,369	239,091,661	6,102,560	247,155,591
Raw (sold or shipped by producers).....	(1)	49,413	(1)	63,195	(1)	64,858
Coke.....	5,277	(1)	6,666	(1)	6,940	(1)
Diatomite.....	(1)	59,581,481	399,070	260,578,749	324,302	255,670,642
Emery.....	389,294	(1)	(1)	(1)	(1)	(1)
Feldspar (crude).....	(1)	(1)	(1)	(1)	(1)	(1)
Ferro-alloys.....	(1)	(1)	(1)	(1)	(1)	(1)
Garnet, abrasive.....	(1)	(1)	(1)	(1)	(1)	(1)
Gems and precious stones.....	(1) (2)	(1) (2)	(1) (2)	(1) (2)	(1) (2)	(1) (2)
Graphite.....	(1)	(1)	(1)	(1)	(1)	(1)
Artificial.....	(1)	(1)	(1)	(1)	(1)	(1)
Crystalline.....	1,012,987	1,605,530	713,961	1,229,796	594,067	1,128,821
Gypsum (crude).....	(1)	(1)	(1)	(1)	(1)	(1)
Iron.....	4,011,238	278,734,591	3,953,462	279,873,775	3,836,078	276,575,005
Ore.....	2,434	326,156	2,355	353,250	1,644	263,040
Pig.....	68,443	552,411	121,890	976,662	193,305	1,410,956
Lead.....	(1)	(1)	(1)	(1)	1,380	565,800
Lime.....	(1)	(1)	(1)	(1)	(1)	(1)
Magnetite.....	(1)	(1)	(1)	(1)	(1)	(1)
Manganese.....	(1)	(1)	(1)	(1)	(1)	(1)
Marble.....	(1)	(1)	(1)	(1)	(1)	(1)
Mineral waters.....	(1)	(1)	(1)	(1)	(1)	(1)
Natural gas.....	8,718,000	6,498,000	8,062,000	5,994,000	7,600,000	5,587,000
Natural gasoline.....	15,000	1,000	12,000	1,000	12,000	1,000
Ores (crude), etc.....	(1)	(1)	(1)	(1)	(1)	(1)
Zinc.....	167,923	(1)	154,001	(1)	120,106	(1)
Pearl.....	380,863	(1)	359,944	(1)	303,451	(1)
Petroleum.....	9,000	41,000	(1)	(1)	(1)	(1)
Perlite.....	5,421,000	16,000,000	5,059,000	15,230,000	4,697,000	15,600,000
Salt.....	68,896	250,527	62,907	227,723	(1)	(1)
Sand.....	2,792,670	8,118,147	2,926,388	9,328,672	2,925,675	9,899,580
Sand and gravel.....	16,286,367	11,841,245	17,375,378	7,260,547	7,049,583	4,308,390

Mineral products of the United States, 1948-44, by States—Continued

NORTH CAROLINA—Continued

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value
Quartz crystal..... pounds						
Sand and gravel..... short tons	4, 280, 198	\$2, 491, 820	3, 046, 168	\$1, 323, 516	2, 535, 601	\$1, 405, 917
Sand and sandstone (ground)..... do						
Silica (quartz)..... do						
Silver..... troy ounces	(1)	(1)	(1)	(1)	(1)	(1)
Stone..... short tons	8, 259	5, 873	7, 160	5, 068	1, 461	1, 039
Talc, pyrophyllite, and ground soapstone..... do	3, 039, 580	2, 774, 472	4, 871, 260	5, 378, 900	4, 659, 540	5, 973, 951
Tantalum and columbium ores: Columblum ore..... pounds	56, 909	563, 062	65, 698	580, 106	60, 892	645, 156
Tin (metallic equivalent)..... do			4, 219	1, 055		
Tungsten concentrates: Ilmenite..... short tons	(1)	(1)	(1)	(1)	100	50
Tungsten ores (60-percent concentrates)..... do					16, 323	224, 680
Vermiculite..... do	1, 612	19, 124, 101	(1)	(1)	18, 186	(1)
Miscellaneous..... do					(1)	(1)
Total value, eliminating duplications.....		17, 372, 690		23, 897, 592		10, 998, 601
				22, 172, 000		22, 199, 000

1 Value included under "Miscellaneous."

2 Value not included in total value for State.

3 Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.

4 No canvass.

5 Not valued as ore; value of recoverable metal content included under the metals.

6 Figures not available.

7 Includes minerals indicated by "1" above.

NORTH DAKOTA

Clay:						
Products (other than pottery and refractories).....						
Raw (sold or shipped by producers)..... short tons	(1)	(1)	(1)	(1)	(1)	(1)
Coal..... do	2, 537, 016	\$3, 554, 000	2, 500, 202	\$3, 752, 000	2, 490, 000	\$3, 810, 000
Mineral waters..... do	(1)	(1)	(1)	(1)	(1)	(1)
Natural gas..... gallons sold	122, 000	40, 000	177, 000	60, 000	200, 000	68, 000
Sand and gravel..... short tons	2, 509, 684	343, 612	1, 459, 232	550, 263	2, 127, 029	733, 340
Stone..... do	(1)	(1)				
Miscellaneous..... do		90, 396		60, 024		60, 024
Total value, eliminating duplications.....		4, 028, 008		4, 422, 000		4, 671, 000

1 Value included under "Miscellaneous."

2 Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.

3 No canvass.

4 Includes minerals indicated by "1" above.

Value included under "Miscellaneous."

¹ Value included under "Miscellaneous."

- ; Exclusive of natural cement, value for which is included under "Miscellaneous."
- ; Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.

g certain classes of clay products.
Value not included in total value for State.

No can pass.

No can vass. value for which is included under "Miscellaneous."

**Exclusive of unclassified stone,
From incising operation.**

* From zinc-roasting operation.
† Includes minerals indicated by "1," "3," and "4" above.

Mineral products of the United States, 1942-44, by States—Continued

OKLAHOMA

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value
Asphalt (native).....	(1)	(1)	(1)	(1)	(1)	(1)

See footnotes at end of State table.									

1 Exclusive of natural cement, value for which is included under "Miscellaneous."
 2 Exclusive of dimension basalt in 1942 and 1943 and of crushed granite in 1944, value for which is included under "Miscellaneous."
 3 From zinc smelting.
 4 Includes minerals indicated by "i," "o," and "p" above.

1 Exclusive of natural cement, value for which is included under "Miscellaneous."

Value included under "Miscellaneous."
 Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.
 No canvases.

TENNESSEE

[illegible]

See footnotes at end of State table.

Mineral products of the United States, 1942-44, by States—Continued

TENNESSEE—Continued

Product	1942		1943		1944	
	Quantity	Value	Quantity	Value	Quantity	Value
Pyrites.....long tons.	(1)	\$3,650,427	(1)	2,922,762	(1)	2,794,167
Sand and gravel.....short tons.	(1)	\$2,064,490	(1)	\$2,285,339	(1)	\$2,314,478
Silica (quartz).....do.	(1)	34,671	(1)	37,019	(1)	45,907
Silver.....troy ounces.	(1)	7,716,540	(1)	8,280,320	(1)	7,776,776
Stones.....do.	(1)	9,018,272	(1)	10,047,944	(1)	32,645
Strontium minerals.....do.	(1)	43,971	(1)	41,766	(1)	40,881
Sulfuric acid.....do.	(1)	8,178,606	(1)	9,021,456	(1)	9,309,468
Zinc.....do.	(1)	60,170,344	(1)	64,836,623	(1)	54,324,215
Miscellaneous.....do.	(1)	67,228,639	(1)	64,465,000	(1)	63,282,000
Total value, eliminating duplications.....						

* Value included under "Miscellaneous."

* Value not included in total value for State.

* Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.

* No canvass.

* Not valued as ore; value of recoverable metal content included under the metals.

* "Commercial." Value of "Government-and-contractor" included under "Miscellaneous."
 * Exclusive of crushed sandstone, value for which is included under "Miscellaneous."
 * From copper smelting.
 * Includes minerals indicated by "i," "a," and "r" above.

† Not valued as ore; value of recoverable metal content included under the metals.
 ‡ Exclusive of basalt and dimension unclassified stone, value for which is included under "Miscellaneous."
 § From zinc smelting.
 ¶ Includes minerals indicated by "q" and "r" above.
 * Value included under "Miscellaneous."
 † Estimate by Bureau of Mines based on figures issued by Bureau of the Census covering certain classes of clay products.
 ‡ Value not included in total value for State.
 § No canvass.
 ¶ Figures cover fiscal year ended June 30 of year stated.

GENERAL SUMMARY

Although it might have seemed that the gold industry in the United States had reached bottom in 1943, such was not the case, for mine production in 1944 continued to decline sharply and totaled less than a million ounces—27 percent under the 1943 figure—for the first year since 1847. The number of gold mines in operation decreased further, as did employment, and gold output became more and more a by-product of base-metal mining. The issuance of Government permits for the limited production of gold under Order L-208 had little effect in increasing the output, as labor and supplies were virtually unobtainable, and decreased base-metal production and a lower gold content of base-metal ores lowered further the yield from this source.

Reduced output of gold from the 1943 figure was general over the world, averaging an estimated 8 percent. Canadian production dropped 22 percent; South African, 4; Nicaraguan, 10; Australian, 16; Indian, 26; and Gold Coast, 8; Brazil, Colombia, Mexico, Peru, and Venezuela also showed decreases.

Silver output in the United States in 1944 likewise declined from that in 1943—17 percent. Production from base-metal ores was maintained at more than 80 percent of the 1943 rate, but dry and siliceous ore contributed little more than half the quantity from this source in 1943. Output in Canada was down 21 percent. Mexican production slumped appreciably—14 percent—but output from Peru rose 7 percent.

LEGISLATION AND REGULATIONS

Gold.—Following an increase in the amount of gold entering neutral countries from Germany, the Treasury Department in February issued a regulation declaring that thereafter the United States would not buy any gold located outside of the territorial limits of the United States from any country that had not broken relations with the Axis or from any country that after the date of this regulation acquired gold from any country that had not broken relations with the Axis. Provision was made, however, for recognition of the title if the United States were fully satisfied that the gold in question had not been acquired directly or indirectly from Axis Powers. The United Kingdom and Russia made similar declarations governing looted gold.

On September 1 a bill was introduced into both branches of Congress to "permit the sale in foreign markets of newly mined gold or silver produced within the United States, its Territories and possessions, including Alaska, and which may be surplus to the war effort." The bill was designed primarily to permit domestic producers of gold to

the advantage of the high price for the metal in the Indian market, but it was quickly pointed out that because of existing exchange conditions sales of United States gold, over and above the rupee needs of our military forces, would produce only rupee credits which could not now be converted. Hence the bill would have worked to the detriment rather than to the benefit of American gold producers.

In October the War Production Board granted authority to gold mines to purchase equipment and materials for rehabilitating their properties so that operations could be resumed as soon as Order L-208 was canceled, but following military reverses on the western front late in the year and the consequent resumption of full wartime production the board announced that action on gold mines would be delayed.

Silver.—Wartime restrictions on the silver industry continued throughout 1944, with certain modifications from time to time. On June 1 the Office of Price Administration issued Revised Maximum Price Regulation 198 establishing consolidated and simplified controls of silver prices and quantity price ceilings on sales of commercial bars by refiners and others. On December 20 the President signed the 1-year extension of the Green Act relating to the use of Treasury silver for domestic consumption.

MONETARY AND ECONOMIC CONSIDERATIONS

The years between World Wars I and II witnessed many kinds of economic hostilities and monetary upheavals between numerous nations. Realizing the crying need for commercial policies designed to facilitate orderly revival and expansion of international trade and to establish proper trading practices in the postwar period, representatives of 44 United and Associated Nations assembled at Bretton Woods N. H., in July 1944 to formulate plans for setting up a permanent agency to deal with the many problems bound to arise in this respect. The texts of the proposals are voluminous, the language is involved and technical, certain statements are clouded and difficult of interpretation, and many controversial details are avoided; yet the proposals represent the first tentative steps toward establishing trade and investments on a sound basis among nations after the war and avoiding some of the treacherous economic and monetary pitfalls that followed World War I. The agreements, in draft form, were submitted to the various governments, none of which was bound to accept them.

Two important provisions of the agreements are emphasized, one for the establishment of an International Monetary Fund and the other for the establishment of an International Bank for Reconstruction and Development.

The aims of the Fund are to promote exchange and currency stability as a means of restoring world trade, to establish a procedure for changing exchange rates when necessary, to eliminate such destructive practices as indiscriminate exchange restrictions, multiple currency practices, and bilateral clearing agreements, to assure member countries that the proceeds of sales to any one member can be used for the purchase of goods from any other member, and to re-establish international currencies on a gold basis, seemingly as a form of modified gold standard.

The Fund is intended to operate on a short-loan basis, to provide a revolving fund to meet temporary shortages in the balance of payments of the member countries. It was pointed out that such a fund cannot be used in the hope of curing the basic economic ills of a nation but at best can only tide over the country for the time being; and that in the final analysis currency stability is not a matter of monetary mechanisms alone but depends primarily on a stable government and sound internal economic policies; hence, it begins at home.

Holdings for the Fund would be built through assigned member quotas in gold and national currencies and would total \$8,800,000,000 for the countries represented at the conference. The gold part of the subscription would be a minimum of 25 percent of the country's quota or 10 percent of its net official holdings of gold and United States dollars, whichever is smaller. The quota of the United States was placed at \$2,750,000,000, of which about \$687,500,000 would be required in gold.

Among the more important objections that have been voiced against the plan may be mentioned the following: The plan seeks to substitute a managed paper currency for the tried and tested gold and silver standards; the proposals seem grandiose and overambitious; too much emphasis is placed on the financial and credit machinery of stabilization and too little on the underlying essentials of sound internal economies and liberal trade policies; the plan is weak in its system of quotas and rights to start borrowing without question of credit worthiness from a large general fund; the proposals should contain more definite commitments on the maintenance of exchange stability and abandonment of exchange restrictions; creditor countries, particularly the United States, are concerned about having adequate safeguards against abuse of the Fund's resources; the Fund's holdings are larger than is necessary and under proper organization and management could be reduced to half this amount and still accomplish the same purposes.

Early in 1945 a movement was made to have the plan approved at once by the Congress, but the opposition countered with the proposal that it would be better to hold another conference in an effort to clear up some of the objectionable features mentioned above.

The proposed International Bank for Reconstruction and Development would operate on a basis of long-term productive foreign loans to member countries. Its broad objectives would be to assist reconstruction and development of territories of members; to promote foreign investment by means of guarantees or participations in loans; to promote the long-range balanced growth of international trade and the maintenance of equilibrium in balances of payments; to arrange the loans made or guaranteed by it in relation to international loans; and to conduct its operations with due regard to the effect of international investment on business conditions in the territories of members.

To promote this international flow of long-term capital the International Bank would be provided with \$10,000,000,000, but initial payments of each member country would be limited to 20 percent of its quota. The balance of 80 percent would be called only as needed.

The Bank's organization was considered by many to be simpler and more understandable than that for the Fund and appears to have

been received more favorably in many quarters. It was stated to be as ambitious in lending power than the Fund and also in provisions to safeguard individual credits. However, the question was raised as to the \$10,000,000,000 capital might be larger than necessary in view of the large gold and dollar resources now held by many countries.

POSTWAR OUTLOOK

The postwar outlook for gold continues dark and appears to have brightened but little during the past year. (See *Minerals Yearbook*, 1945, pp. 94-95.) The situation has worsened to the extent that the War Production Board Limitation Order L-208 was not revoked until July 1, 1945; consequently, many closed mines continued to operate in 1944. Also, wholesale commodity prices (1926=100) rose from 103 in 1943 to 104 in 1944, thereby reducing further the purchasing power of the gold ounce, and relief from numerous other increases in the cost of mining is not in prospect. Even the hope was held for an increase in the price of gold, upon which the future of the industry depends so greatly, received scant support from the Congress and Government monetary experts. On the other hand, officials in some countries, Union of South Africa, for example, have stated that a free market for gold is a requirement in any postwar arrangement, under which it is believed that a much greater price for the metal would be obtained. The extent and influence of such a movement cannot be predicted at this time.

Concerning the outlook for the domestic industry, Merrill¹ writes as follows:

If the postwar period price level is stabilized well above the average during the period 1935-40 and if gold remains at \$35 per ounce, the outlook for the domestic gold miner will be gloomy indeed. Not only would the gold industry be in an economic situation similar to that in the twenties, but it would enter the period with its mines largely idle and in disrepair; many operating companies would not have enough funds to finance resumption of production. A substantial stabilization of the industry seems to lie largely with the gold price higher than \$35 an ounce, but this possibility cannot now be appraised with assurance.

Regarding the relation between the price of gold and the high cost of producing it, Needham² makes the following comments:

Virtually every factor in the cost of mining gold has increased. Advances in the cost of supplies are indicated by the rise in the wholesale commodity index (1906=100) from 66 in 1939 to 103 in 1943. The cost of labor likewise has increased. * * * Taxes and insurance costs are considerably higher than in former days and are likely to continue at a high level in postwar years. * * * Mechanization doubtless will expand in the future, but the present outlook is that only moderate savings in unit labor costs can be anticipated. Barring fortuitous discoveries of high-grade deposits the average grade of gold ore mined will continue the downward trend evident in the past. From the long range few major reductions in other cost items such as taxes and supplies are not in sight. It may be said therefore that the cost of producing gold in the United States, which already has undergone a large increase since the early 1930's, seems likely to increase for some time to come if a substantial volume of production is maintained.

Although the postwar outlook for silver is reasonably good, for a number of reasons the industry is not likely to return to the prosperous

¹Merrill, Charles White, *War and Gold*: Eng. and Min. Jour., vol. 146, May 1945, p. 89.
²Needham, C. E., *The Gold Industry of the United States*: Min. and Ind. Mag. of South Africa, vol. 8, No. 2, February 1945, pp. 109, 111; *South African Min. and Eng. Jour.*, vol. 56, Mar. 10, 1945, pp. 35, 37.

period of 1940-41 unless the price of the metal is increased or the volume of base-metal output is maintained at a very high rate.

Delegates to the Bretton Woods Conference evinced little interest in extending the monetary use of silver, and until public opinion undergoes a changed attitude toward the silver question it seems unlikely that any appreciable increase, if indeed any at all, in the price of the metal will be made in the immediate postwar period.

It is believed that in the postwar epoch Government policy will favor reduced tariffs and that some base metals will be included in the new schedules. This reduction, coupled with declining reserves and the general lower tenor of base-metal ores, is expected to bring about a reduced output of base metals and of the silver derived from them. However, the base-metal industry will continue to supply a large and important part of domestic silver output.

Many mines that operated largely or entirely on dry and siliceous silver ore have closed during the war because of high mining costs, a fixed price for the metal, and inability to procure labor and supplies. Many of these will not reopen after the war; those that do reopen will face continued high costs of production, deteriorated mines, and insufficient developed ore. Consequently, it is quite unlikely that output from this source will return to its prewar level unless the price of silver is increased.

The industrial demands for silver after the war should continue strong compared with the prewar period. It has been found that silver is particularly well adapted to many industrial uses, many of which will be retained in the future. However, the extent to which the metal is used in industry depends much on its being low enough in price that substitutes do not crowd it out.

In conclusion it may be said that the future of the silver industry rests largely on the two factors of Government price and the price of copper, lead, and zinc.

DOMESTIC REFINERY PRODUCTION

The figures in the following table were obtained through cooperation between the United States Bureau of the Mint and the Bureau of Mines and were agreed upon after conference and adjustment between the two Bureaus.

The State totals are based upon bullion deposits in the United States mints and assay offices and upon returns to the Bureau of the Mint from smelting and refining companies. The state distribution is adjusted further by the Bureau of Mines from its geographical records of sources and production, both historical and current, from the producing mines and is tabulated for the mine reports discussed later. The data for the total production and in part for the distribution are obtained from records of (1) the unrefined domestic gold and silver deposited in the United States mints and assay offices; (2) the domestic gold and silver in fine bars reported by private refineries, supplemented by data of content of unrefined mattes, blister copper, copper anodes, and lead bullion; and (3) the unrefined domestic gold and silver contained in ore and matte exported for reduction. The last item is small.

Gold and silver produced in the United States, 1940-44, and approximate distribution of source, by States and Territories, in 1944

[Refinery figures supplied by U. S. Bureau of the Mint]

State or Territory	Gold ¹		Silver ¹

¹Gold valued at \$35 a fine ounce.

²Silver valued at \$0.711+ a fine ounce.

Gold and silver produced in the United States, 1792-1944

From Report of the Director of the Mint. The estimate for 1792-1873 is by R. W. Raymond, commissioner of mining statistics, and since then by the Director of the Mint]

Period	Gold		Silver	
	Fine ounces	Value ¹	Fine ounces	Value ¹
1792-96	1,187,170	\$24,537,000	309,500	\$404,500
1897-1900	58,279,778	1,204,750,000	118,568,200	157,749,900
1901-1904	214,110,795	5,066,675,100	3,743,073,719	2,809,647,066
	273,583,743	6,295,962,100	3,861,951,419	2,967,801,466

¹Gold valued in 1934 and thereafter at \$35 per fine ounce; prior thereto at \$20.67+ per fine ounce. Dollar figures rounded.

²Silver valued in 1934 and thereafter at Government's average buying price for domestic product: In 1934 at \$0.64+ per fine ounce, in 1935 at \$0.71875, in 1936 at \$0.7745, in 1937 at \$0.7735, in 1939 at \$0.678787+, in 1940-44 at \$0.7111+.

PRICES OF GOLD AND SILVER

Since January 1934 the price of gold at the United States Mint has been \$35 per fine troy ounce; the price of domestic silver mined after July 1, 1939, was fixed at \$0.711+ per ounce on July 6, 1939. A complete account of regulations pertaining to gold and silver in 1933-34 is given in the chapter on Gold and Silver in Minerals Yearbook, 1934 (pp. 25-46).

According to the Director of the Mint, the following prices for silver prevailed in London and New York throughout 1944: London price per ounce, 0.925 fine, 23.5 d.; exchange, New York on London, \$4.0350; United States equivalent, per fine ounce, of London price at current rate of exchange, \$0.42713; New York price of fine bar silver, \$0.45062.

UNITED STATES AND WORLD MONETARY STOCKS

Gold holdings of the United States dropped \$1,319,000,000 (1 percent) from \$21,938,000,000 on January 1, 1944, to \$20,619,000,000 on January 1, 1945, according to the Federal Reserve Bulletin. Total world reserves are not positively known, inasmuch as data are not available from a number of countries, including the United Kingdom, Germany, Italy, Japan, Australia, and Russia. However, the Federal Reserve System estimates the total at about \$35,000,000,000, of which nearly 60 percent is held by the United States.

Increases in foreign gold reserves have been rapid since the United States entered the war late in 1941, largely because our gold is being lost to the countries that have export trade balances with us. In this time foreign reserves have increased more than \$5,000,000,000, and United States reserves have declined \$2,000,000,000. Sharing prominently in this increase are Switzerland, Sweden, Turkey, Iran, Portugal, Spain, South Africa, and the Latin American countries.

As a result, many foreign countries will enter the postwar period well-supplied with gold, and these reserves promise to be an element of strength in rehabilitating war-torn Europe.

United States Treasury silver holdings declined considerably more rapidly in 1944 than in 1943, the loss reaching nearly 255,000,000 ounces, so that at the close of the year silver reserves approximated 2,999,000,000 ounces.

The Twenty-ninth Annual Review of the Silver Market, 1944, by Handy and Harman, contains the following comments on Treasury purchases, sales, and domestic coinage:

For the second successive year since the inauguration of the silver purchase program in 1934, United States Government silver holdings showed a decrease, bringing the amount on hand at November 30, 1944, down to just below 3 billion ounces. The reduction in 1943 amounted to 85,300,000 ounces, but for the first 11 months of 1944 it was three times as large; namely, 254,700,000 ounces. This amount was a net figure consisting of 255,000,000 ounces released and less than 300,000 ounces acquired. The acquisitions represented 119,528 ounces of newly mined domestic silver and 151,669 ounces of miscellaneous deposits received at the mints and assay offices. No foreign silver was purchased. Treasury disposals during the 11-month period were comprised as follows: The minting of "silver" nickels accounted for 8,489,000 ounces; sales under the Green Act absorbed 43,672,000 ounces; lend-lease procedure made 202,807,000 ounces available to foreign governments, a total of 255,000,000 ounces. The governments receiving lend-leased silver were Australia, Ethiopia, Great Britain, India, the Netherlands, and Saudi Arabia.

According to the Treasury's Daily Statement dated December 30, 1944, there were 1,175,700 ounces of silver pledged as backing for silver certificates and 868,700,000 ounces which remained unpledged. Of this, 2,044,400,000 ounces of Government-owned bullion, the Defense Plant Corporation, etc., held 880,000,000 ounces, an amount which was 51,000,000 ounces more than at the end of 1943, but 22,000,000 ounces less than the peak recorded early in 1944.

Domestic coinage in the United States declined below the record figure established in 1943. As compared with that year's consumption of 98,485,000 ounces,

In 11 months of 1944 absorbed only 64,496,000 ounces according to official figures, a decrease of nearly 35 percent. As previously mentioned, 8,489,000 ounces were minted into "silver" nickles and the balance of 56,007,000 ounces into half-dollars, quarters and dimes. Foreign coinage produced by United States Mints during the first 11 months consumed 79,102,000 ounces of silver, of which 12,048,000 ounces were furnished by other governments. The remaining 67,054,000 ounces were made available under lend-lease and represented part of the 11,807,000 ounces derived from that source. The Governments for which the coins were minted in 1944 were Australia, Dominican Republic, El Salvador, Ethiopia, the Netherlands, Philippine Islands and Saudi Arabia.

CONSUMPTION AND USES

Silver.—War and other essential uses consumed an estimated 70,000 to 85,000,000 ounces of silver in 1944. Solders and brazing alloys were used extensively in almost all important military equipment, occupied first place. Following closely for war purposes were photographic applications, electrical appliances, engine bearings, and military insignia. Appreciable quantities continued to be absorbed in making eating utensils for the armed forces, desalination equipment, dental and medical supplies. Consumption declined in civilian uses and also in low-melting solders.

For allocation the War Production Board divided silver into three classes: Treasury, domestic, and foreign.

Treasury silver was eligible for engine bearings, official military insignia, solders and brazing alloys, identification neck chains, and desalination kits. Domestic silver was permitted in silverware, jewelry, watch cases, church articles, pens and pencils, mirrors, and other items classed as nonessential. Foreign silver was limited to photographic uses, electrical appliances, medical and dental supplies, and other items and processes bearing preference ratings.

Although imports declined from 1943, supplies of foreign silver in 1944 were more than sufficient for the uses specified by the War Production Board, and a considerable surplus accumulated. On the other hand domestic silver was in short supply, and much criticism was directed at the Board for alleged refusal to follow the spirit and the letter of the Green Act in making Treasury silver available for civilian needs. Consequently, by fall it became necessary for suppliers to ration regular users of silver far below the 50-percent quota established by the Board.

Late in the year Secretary Morgenthau announced that since Pearl Harbor silver transactions under Treasury policy were as follows: Under lease arrangements for nonconsumptive uses in war plants, 903,000,000 ounces; supplied to various governments under lend-lease for coinage and other war uses, 243,700,000 ounces; sold from "silver primary" stock to industrial users, 5,000,000 ounces; sold under the Green Act, 41,000,000 ounces; for coinage in "silver nickels," 33,600,000 ounces.

Earlier, the Secretary also announced that through a special lend-lease agreement India would be supplied with 100,000,000 ounces of silver to be used for additional coinage and expanded war production, and to help stabilize prices in the fight against inflation. After the war the metal will be returned ounce for ounce.

*Net industrial consumption of gold and silver in the United States, 1940-44*¹

¹ Excess of exports.

DOMESTIC SUPPLY

Base-metal ores in 1944 continued to increase in relative importance as sources of gold and silver, and dry and siliceous ores declined compared with 1943, but placers as a source of gold recovered slightly from the low level of 1943.

Mine production of gold in the United States, 1940-44, by percent from sources, and in total fine ounces¹

MINE REPORT

METHOD OF COLLECTING STATISTICS

The second table in this report presents the official refinery figures for production of gold and silver in the United States from 1940 to 1944, as agreed upon by the Bureau of the Mint and the Bureau of Mines. These figures record the output of gold and silver bullion from domestic ore in marketable form as metals, either refined or unrefined.

To trace the gold and silver produced back to its source by States, counties, and mining districts, the Bureau of Mines systematically investigates the "mine production" of ores containing gold and silver and the output of the placer mines, the total being classified by methods of production and by kinds of ore, as well as by mining districts. The resulting figures form the basis of the mine reports.

Of the two systems for ascertaining the production of gold and silver, one is a measure of the metallurgic industry and the other of the mining industry; one reports the metal actually recovered in marketable form and the other the mine output and its recoverable content. The two methods will not produce identical results, but data for a period of years long enough to compensate for overlap or lag should agree within allowable limits of error.

Compared with the mine reports, the mint reports for the 40 years show a total excess of gold of 338,161 ounces (a difference of 0.24 percent) and a total excess of silver of 13,439,210 ounces (a difference of 0.58 percent).

Gold and silver produced in the United States, 1905-44, in fine ounces, according to mint and mine returns, in terms of recovered metals

Year	Mint		Mine	
	Gold	Silver	Gold	Silver
1905-39.....	124,925,716	2,025,813,631	124,867,875	2,016,347,731
1940.....	6,003,105	69,585,734	5,984,163	71,824,746

1942.....	3,741,806	56,090,855	3,615,836	54,321,962
1943.....	1,394,522	40,900,121	1,377,579	41,486,897
1944.....	1,022,238	35,651,049	998,394	34,473,540
	143,063,806	2,300,377,419	142,725,645	2,286,938,209

UNITS OF MEASUREMENT

All tonnage figures are short tons of 2,000 pounds "dry weight"; that is, they do not include moisture. The weight unit for gold and silver is the troy ounce (480 grains). The totals are calculated upon the basis of recovered and recoverable fine gold and silver shown by assays to be contained in ore, bullion, and other material produced. Prices of gold and silver are discussed in a preceding section of this report.

NUMBER OF MINES

The following table indicates the number of mines that produced gold and silver in 1943 and 1944. The placers are those in which gold and silver in natural alloy and, in a few placers, platinum are recovered from gravel and sand, whether by hand washing, sluicing, hydraulicking, drifting (in frozen ground or ancient buried river channels), or dredging. The lode mines are those yielding gold and silver from ore as distinguished from gravel, mainly from underground workings, and include those that yield ore mined chiefly for copper, lead, or zinc but that contribute the precious metals as byproducts. As far as possible the unit is not the operator but the mining claim or group of claims.

Number of mines in the United States producing gold or silver, 1943-44, by States

ORE PRODUCTION, CLASSIFICATION, METAL YIELD, AND METHODS OF RECOVERY

The best index of lode mining is the quantity and metallic content of ore mined rather than the number of mines or operators. The following tables give details of classes of ore, metal yield in fine ounces of gold and silver to the ton, and gold and silver output by classes of ore and by methods of recovery, embracing all ores that yielded gold and silver in the United States (excluding the Philippine Islands and Puerto Rico) in 1944. The individual State chapters from which these tables were compiled contain additional tables and text on the subject and may be found elsewhere in this volume.

The classification originally adopted in 1905 on the basis of smelter terminology, smelter settlement contracts, and smelter recovery has been used continuously in succeeding years, except for modifications necessitated by the improvement in recovery of metals and the lowering of grade of complex ores treated, accomplished by improved mill concentration processes. A "dry" ore is one that carries so little lead or copper that by itself in quantity it would not satisfy the requirements for the smelter charge in lead smelting or copper smelting, respectively. The copper ores include those smelting ores that contain 2.5 percent dry assay or more of copper (or less than this percentage if no other metal is present), or those ores concentrated chiefly for their copper content. The lead ores are those that contain 5 percent dry assay (minimum lead smelting charge requires 7.5 to 8.5 percent wet assay) or more of lead, irrespective of precious-metal content; an ore that carries any grade of lead exclusively is called a lead ore. Zinc smelting ores (chiefly oxides) range from 16 to 45 percent zinc; zinc concentrating ores include any grade of zinc ore that makes marketable zinc concentrate, irrespective of precious-metal content. The mixed ores are combinations of those enumerated. The smelter classification applies to concentrates.

Siliceous (silica ⁴ in excess of iron) gold, gold-silver, and silver ores ¹ have where mineralization approaches a matte, ores in their natural state generally contain more silica than iron and usually are highly siliceous.

containing too little copper, lead, or zinc to be classified as copper, lead, zinc, or mixed ores are called "dry" ores regardless of the ratio of concentration, except low-grade ore milled chiefly for its copper content and having very little or no precious-metal content (chiefly

¹Excludes Michigan, Missouri, Philippine Islands, and Puerto Rico excluded.

²Less than 0.005 ounce per ton.

³Excludes zinc-copper and zinc-lead-copper ore from Arizona.

⁴Includes 115,281 tons of zinc slag from which silver was recovered.

⁵Includes 157,968 tons of zinc slag from which silver was recovered.

⁶Includes 6,990 tons of zinc slag from which gold and silver were recovered.

⁷Excludes magnetite-pyrite-chalcoppyrite ore from Pennsylvania.

the "porphyry coppers") and ores from which separate products of lead concentrates and zinc concentrates are made. The crude ore into the mill in these two exceptional instances thus takes its name from its products—a name that is also justified by the mineralogical content and final recovery of metals. The "dry and siliceous ores" thus, by elimination, include both dry siliceous and iron, but chiefly siliceous, ores valuable for their gold and silver content, regardless of method of treatment, and dry fluxing ores carrying considerable quantities of iron and manganese oxides, or iron sulfide, and very small quantities of gold and silver. Dry and siliceous gold ores are those that by inspection are overwhelmingly of gold content; a similar qualification applies to silver ores; decision as to "gold-silver" ore is made arbitrarily on a basis of value, using the rule that the metal of lower value is not used in the bimetal classification unless its value is equal to or over one-quarter of the combined value of the gold and silver.

The lead, zinc, and zinc-lead ores in most districts in the Eastern and Central States carry no appreciable quantity of gold or silver; such ores are excluded from this report unless otherwise indicated.

Mine production of gold in the United States in 1944, by States and sources, in fine ounces, in terms of recovered metals ¹

¹ Illinois, Michigan, Missouri, Philippine Islands, and Puerto Rico excluded.

² Comprises 113,869 tons of sands and slimes from ore first roasted and amalgamated and 86,145 tons of selective-flotation tailings.

³ Less than 0.005 percent.

⁴ No ore treated; bullion produced in clean-up at Homestake mill.

PLACERS

Most of the placer gold produced is obtained from gravels handled by connected-bucket floating dredges. In 1944 this method recovered 69 percent of the total output from placers in the United States compared with 69 percent in 1943. The quantity of gold recovered by dredges from the inception of the industry as a commercial factor in 1860 to the end of 1944 is recorded as 19,285,976 ounces, originating in States as follows: California, 11,698,840 ounces; Alaska, 5,202,898 ounces; including the production from single-dipper dredges and some gold dredging by hydraulicking; Montana, 708,244; Idaho, 612,271; Colorado, 552,195; Oregon, 467,046; other States, 141,487.

The following table shows the gold produced in the United States by connected-bucket floating dredges in 1940-44.

Additional information on placer mining may be found in the State reviews in this volume.

Gold produced in the United States by connected-bucket floating dredges, 1940-44, in fine ounces

Year	Dredges	California	Alaska	Other States ¹	Total
1940	122	414,966	354,806	134,377	904,149

1944	19	64,925	26,280	10,774	101,979

¹ Colorado, Idaho, Montana, Nevada, and Oregon.

EMPLOYMENT AND PRODUCTION IN 1943

Many of the trends characterizing the industry in 1942 continued at an accelerated pace in 1943. The number of mines producing gold and silver ores, the men employed and the man-hours of labor performed declined 70 percent from 1942; operating days per mine increased from 248 days in 1942 to 279 in 1943; average workyear per man from 1,986 man-hours to 2,231, and tons of ore produced per mine from 6,334 to 7,474; man-hours per ton of ore mined declined from 2.19 to 2.15.

¹ Preliminary world gold-production table prepared, with revisions and adjustments, by B. B. Waldbauer and J. R. Kelghley, Foreign Minerals Division, Bureau of Mines, in cooperation with the Office of the Director of the Mint. Figures used were derived in part from the Statistical Yearbook of the League of Nations and from the American Bureau of Metal Statistics. No official statistics are issued by Government of U. S. S. R., consequently figures released by the various authorities vary widely and are irreconcilable. In some countries accurate figures are not possible to obtain owing to clandestine trade in gold.

² Refinery production.

³ Imports into United States.

⁴ Exports.

⁵ Data not available. Estimate included in total.

⁶ Approximate production.

⁷ Purchases by the State Central Bank.

⁸ Conjectural figure published by the American Bureau of Metal Statistics (New York), Annual Issue.

⁹ Beginning with 1939, Burmese production included with British India.

¹⁰ Figure published by the Director of the Mint, representing gold of Philippine origin refined but not necessarily mined during the year.

¹¹ Beginning with 1941, production of Ruanda and Urundi included with Belgian Congo.

¹² Exclusive of nonmembers of the Transvaal Chamber of Mines.

¹³ Includes New South Wales, Northern Territory, Queensland, South Australia, Tasmania, Victoria and Western Australia.

⁸ Includes New South Wales, Northern Territory, Queensland, South Australia, Tasmania, Victoria and West Australia.

REVIEW BY COUNTRIES

CANADA

Canadian output of gold and silver in 1944 continued to drop from 1943—gold 22 percent and silver 21 percent; gold output totaled scarcely more than half that of the record year 1941. Production by sources remained in about the same ratio—83 percent from quartz lodes and placers and 17 percent from base metals. Output of gold and silver in 1944 was distributed among the various Provinces as follows:

Province:	Gold, fine ounces	Silver, fine ounces
Alberta.....	51	—
British Columbia.....	191,423	5,600,242
Manitoba.....	74,665	661,893
Northwest Territories.....	20,739	5,428
Nova Scotia.....	5,859	190
Ontario.....	1,704,457	2,986,479
Quebec.....	740,744	2,558,308
Saskatchewan.....	123,230	1,741,227
Yukon.....	24,306	32,735
Total.....	2,885,474	13,586,502

The labor situation continued bad. During the year employment in the gold lode mines dropped 6 percent from 16,400 at the beginning of the year to 15,400 at the close. It was stated that many mines had deteriorated to such an extent that after the war 2 years might be required to put them in condition for normal employment. Special acts were made by Ontario to keep cities and towns solvent, and *York Township* was placed under Provincial supervision.

The year witnessed a tremendous revival in prospecting. Hundreds of new companies and syndicates were formed to acquire holdings in all the way from northwestern Quebec to Yellowknife in the Northwest Territories, and trading in gold stocks on the Toronto exchange was very active. However, actual operations were limited by the Government to surface work and diamond drilling.

CENTRAL AMERICA

El Salvador.—Four mines produce most of the gold and silver from this country. All the metal is shipped to the United States for refining.

Nicaragua.—The gold-mining industry in Nicaragua is reported to have employed about 7,000 men in 1944 and to have produced 10 percent of the Government's tax revenue, or about \$500,000; it also provided 60 percent of the nation's export value.

SOUTH AMERICA

Brazil.—Gold output in Brazil in 1944 is reported to have been restricted mainly because of transportation difficulties and a short labor supply. The St. John d'El Rey Mining Co., by far the most important producer, is stated to have ore reserves of 9,453,000 tons averaging 11.8 grams of gold per ton, or about 3,600,000 ounces of gold, of which 65 percent is at the Morro Velho mine. The ore mined by the company in 1943 carried 12.2 grams of gold per ton. Considerable arsenic is also being recovered.

Chile.—Lodes continued to supply nearly 98 percent of Chile's gold, and sources were about equally divided between copper ores and gold ores.

Venezuela.—Gold mines in Venezuela in 1944 were adversely affected by curtailed development resulting from lack of equipment and restrictions on imports from the United States and Great Britain. Ore milled by New Gold fields of Venezuela, Ltd., was less than half the quantity milled in 1942. Also, the grade of ore has fallen so that the company is reported to be operating at a loss.

AFRICA

Union of South Africa.—Output of gold in the Union was maintained at a high rate in 1944, and production declined less than 4 percent from 1943. Profits and dividends, however, continued to drop, profits reaching a point 20 percent below 1940 and dividends 27 percent below.

The steady increase in working and milling costs and the decline in working profit and grade of ore have created a very unfavorable situation for a number of mines in the Union. Early in 1944 the Van Ryn Deep Gold Mining Co., the Witwatersrand Deep Gold Mining Co., and the Geldenhuis Deep Gold Mining Co. gave notice that they

would close in a short time. Other mines, among them the New Modderfontain and the Langlaagte Estate, were also approaching the limits of profitable operation. In reply to demands from some quarters that marginal mines should be afforded some measure of relief by the Government, the minister of mines asserted that it was bad policy to make other people pay to bolster up a mine or any other industry that could not stand on its own feet; therefore, if a mine could not pay its way it would have to close. But in spite of these unfavorable factors optimism prevailed for the future of the industry, provided that gold retains its purchasing power at a rate not less than existed in 1941 and that the demand for gold continues unlimited as it has through the ages.

Chief among the hopeful signs was the possibility of developing 4 or 5 average-size Rand mines, and possibly 10 to 15 ultimately, in the Orange Free State. The new area, as outlined by much drilling, is about 90 miles long north-south and 30 miles wide east-west; the town of Odendaalrust is near the center. All evidence at hand leaves little doubt that this district will witness outstanding development in the postwar period.

ASIA

India.—Output of gold in India in 1944 dropped nearly 26 percent from 1943, and production of gold ore declined from 651,849 tons in 1943 to 469,884 tons in 1944. One of the chief factors in the decline was the shortage of electric power that resulted when the Government power plant was severely damaged by lightning in May.

AUSTRALIA

Concern was expressed in Australia over the continued decline of gold production in the Commonwealth. The chief causes of the slump were manpower restrictions, high cost of stores and materials, low efficiency of the labor obtainable, and the high percentage of absenteeism. It was stated that the Government had removed and packed much equipment from the gold mines to be shipped to base-metal mines but that a considerable part of such material had not been used. Because of the removals many mines had been forced to close.

It was reported that Wiluna Gold Mines, Ltd., had failed to find profitable ore below the 2,000-foot level; as a consequence, the closing date of the mine might not be far in the future.

SUMMARY

At the beginning of 1944 copper was one of several commodities, supplies of which appeared ample for all war and essential civilian requirements, but as the year ended requirements for the metal were greater than ever before and the possibility loomed that supplies would be deficient during 1945. In January 1944 copper was removed from the list of critical materials (having at one time vied with steel as the most critical metal), but by the end of the year it was again high on the list. For most of 1944 supplies were rising in relation to consumption by permitted uses, and the tendency of the Government in 1943 to make more copper available for uses where substitutes had proved inefficient or costly was continued. The improvement noted was despite the recession in mine, smelter, and refinery outputs below the peak rates that prevailed in 1943; it was due partly to the record imports of refined copper in 1944. During the year battlefield scrap began to arrive from abroad and to contribute to supply. Early in the third quarter of 1944 premature hopes for an early end of the European phase of the war led to fears in some quarters that surpluses rather than shortages would soon plague the market, and prospects for increased allocations of copper for civilian consumption appeared bright. The passage of the Surplus Property Act (described later), effective October 3, relieved anxiety regarding surpluses that were expected to exist at the end of the war. The revised military outlook in the final quarter, following reverses in the European war theater, caused a sharp step-up in the small arms and heavy artillery ammunition programs and in other programs involving large use of copper. The rising demand combined with the falling production rates, removed all ideas of immediate surpluses, threw the supply-requirements relationship out of balance, and left little hope for material increase in civilian consumption allowances in the near future. At the end of 1944 the Government military program called for larger quantities of copper than ever before. As a consequence, all of the chief Government purchase contracts at home and

abroad were continued beyond the end of the year, and new contracts were consummated with Northern Rhodesia and Canada.

Smaller outputs in 1944 at mines, smelters, and refineries in the United States, despite increased mine capacity and the ability of smelters and refineries to make larger contributions, were caused almost entirely by an inadequate labor supply. Thus, mine production amounted to 270,000 tons in the first quarter of 1944, 259,000 in the second, 228,000 in the third, and 213,000 in the fourth. In November and December the output averaged 22 percent below the monthly average of 90,000 tons for January to March, inclusive, even though copper mining received greater stimulation in 1944 than in earlier war years, in one respect at least, as is evidenced by the payment of bonuses on 25 percent of the total output in 1944 compared with 23 percent in 1943 and 11 in 1942. Bonus payments data are shown in detail under Prices.

Features of the foreign trade situation in 1944 included new peak imports of refined copper, continuation of the reduced rate since 1941 in exports of refined copper, and new high record exports of insulated wire and cable. The last-named class of exports exceeded all other copper classes in 1944, including refined copper, which had been dominant since before 1900.

Copper ceiling prices continued in effect throughout 1944 at the levels established in 1941.

Late in 1944 some liberated countries and Spain were trying to place orders in the United States for copper. France was reported to have been allotted 10,000 tons, of which 7,000 were to be refined copper and 3,000 tons fired rifle shells.

Salient statistics of the copper industry in the United States, 1940-44, in short tons

	1940	1941	1942	1943	1944
New copper produced—					
From domestic ores, as reported by—					
Mines	878,086	958,149	1,080,061	1,090,818	972,549
Ore produced:					
Copper ore	169,278,476	178,452,504	192,285,626	198,119,735	191,063,648
Average yield of copper, percent	1.20	1.15	1.09	1.04	1.06
Smelters	909,084	966,072	1,087,991	1,092,939	1,003,379
Percent of world total	(2)	(2)	(2)	(2)	(2)
Refineries	927,239	975,408	1,064,792	1,082,079	973,852
From foreign ores, matte, etc., refinery reports	386,317	419,901	349,769	297,184	247,335
Total new refined, domestic and foreign	1,313,556	1,395,309	1,414,561	1,379,263	1,221,187
Secondary copper recovered from old scrap only	333,890	412,699	427,122	427,521	456,710
Copper content of copper sulfate produced by refiners	5,643	6,984	8,076	7,667	8,269
Total production, new and old and domestic and foreign	1,653,089	1,814,992	1,849,759	1,814,451	1,686,166
Imports (unmanufactured) ¹	491,342	735,545	764,393	716,654	787,219
Refined ²	68,337	346,994	401,436	402,762	492,395
Exports of metallic copper ³	427,650	158,893	210,518	294,456	237,514
Refined (ingots, bars, rods, etc.)	377,108	114,753	131,732	177,341	69,002
Stocks at end of year	334,500	317,500	319,500	309,500	392,000
Refined copper	91,500	77,500	84,000	68,500	81,000
Blister and materials in solution	243,000	240,000	235,500	241,000	311,000
Withdrawals from total supply on domestic account:					
Total new copper	1,008,785	1,641,550	1,678,091	1,621,666	1,632,709
Total new and old copper	1,541,000	2,368,000	2,606,000	2,708,000	2,584,000
Price, average cents per pound	11.3	11.8	⁴ 11.8	⁴ 11.8	⁴ 11.8
World smelter production, new copper	(2)	(2)	(2)	(2)	(2)

¹ Includes old tailings.

² Figures not yet available.

³ Data include copper imported for immediate consumption plus material entering country under bond.

⁴ Total exports of copper, exclusive of ore, concentrates, composition metal, and unrefined copper. Exclusive also of "Other manufactures of copper," for which figures of quantity are not recorded.

⁵ Exclusive of bonus payments of the Metals Reserve Company.

A shortage in brass-mill capacity, particularly of copper-base alloy was pointed out at a meeting of the Electric Industrial Control Industry Advisory Committee in July. Capacity for alloy rod production at that time was 94 million pounds a month, but production averaged only 84 million because of the inadequate supply of labor. The War Production Board advocated the substitution of aluminum where possible and moved to have an aluminum rod mill converted to the production of copper-base alloy. By January 1945 the alloy-rod output reached a new record rate of 101 million pounds, but rod mill facilities were expected to be strained, nonetheless, to meet Army requirements. By the end of 1944 step-ups in the Army ammunition program, coupled with labor shortage, caused a critical situation to develop in regard to brass strip. The wire-mill situation was also described as extremely critical. In a maximum effort to meet the Army's expanded 1945 ammunition program the War Production Board announced in December that all participating brass mills and those copper-wire mills producing field and assault wire had been placed on the National Production Urgency List, that arrangements were being made for the production of brass strip in Canadian mills, that copper-clad steel would be used in the small arms ammunition program, and that the utilization of steel-mill facilities for producing ammunition brass strip was being considered. At a Brass Mill Industry Advisory Committee meeting in December, members pointed out that inadequate manpower was the main obstacle to an increase in over-all alloy-brass strip production to the proposed average of 334 million pounds per month for 1945, which rate represented an increase of 50 percent over operating schedules in December 1944. Requirements for refined copper by the brass and wire mills, foundry and non-C. M. P. consumers in 1944 were estimated by the Copper Division of the War Production Board early in 1945 to have been 1,679,900 short tons as compared with supplies of 1,803,400 tons. Estimates for 1945 were reported at the same time as 1,980,000 and 1,576,000 tons, respectively. Thus, a deficit was in prospect for 1945 despite the anticipated 10-percent increase in supplies. A deficient strip-supply situation in 1944 was expected to become more critical in 1945.

LABOR CONDITIONS

The labor shortages described in the 1943 report of this series continued and were accentuated in 1944 at mines, mills, smelters, refineries, and fabricating plants. In contrast to the action of the Army both in 1943 and 1942 in releasing men for service in copper and other mines, not only was such action lacking in 1944, but draft deferments for copper miners became more difficult to obtain. The declining production rate at the mines (previously mentioned) is attributed chiefly to this problem of labor supply. War Production Board chairman, J. A. Krug, indicated that manpower at copper mines declined from 31,000 to 22,000, or 29 percent, from late 1943 to late 1944. Labor shortages impeded capacity operations at fabricating plants also in 1944, and after the military program was increased in the late fall measures were taken to obtain all possible additional workers by recruitment from less essential industries, by publicizing the great need for workers, by recruitment in recreation centers, and by the importation of workers from Jamaica.

The labor problem did not stop with the foregoing. Late in the year the Army announced that it must have approximately twice as much small caliber ammunition in the first half of 1945 as was previously thought necessary. In this connection Chairman Krug announced that 108,600 workers would be needed in ammunition plants in various areas of production, compared with 49,900 already employed. He said that three core plants would require 3,500 additional workers and that, to supply the above plants, brass-rod mills throughout the country would need 10,000 to 15,000 additional workers.

WAR AGENCY REGULATIONS

There were no major revisions in restriction orders affecting copper and copper-base alloys in 1944, and most of the changes applied to small quantities and to products for which substitutes had proved unsatisfactory because they were inefficient or unduly costly. The Controlled Materials Plan, described in the report of this series for 1942, brought steel, copper, and aluminum into precise, measured supply-requirements balance. The principal copper-control orders are War Production Board M-9, which restricts the acceptance of delivery of specified types of copper and copper-base alloy materials (other than controlled materials) and M-9-c, which restricts and prohibits use in the manufacture of specified items, and the amendments to these orders. A tendency toward greater generosity in allocating copper for civilian consumption in the latter part of the year was reversed at the year-end after the military outlook had grown worse and the military program had expanded enormously.

SURPLUS PROPERTY ACT

The Surplus Property Act, effective October 3, provided that all Government-owned accumulations of certain strategic minerals and metals (including scrap), when determined to be surplus, should be added to the permanent Government stock pile authorized by the act of June 7, 1939. Anxiety regarding the dumping of postwar inventories was partly relieved by this action, which, in effect, freezes until January 1946 the entire Government surplus of copper and a number of other metals that may be on hand at the end of the war. Permanent stock-pile legislation was under consideration by the Seventy-ninth Congress.

FOREIGN ECONOMIC ADMINISTRATION PURCHASES

The Foreign Economic Administration was created by an Executive order issued September 25, 1943, and one main function of the new organization was the procurement of minerals from abroad. Alan M. Bateman, in an address on the Postwar Position of World Minerals in New York, February 19, 1945, said that only 20 percent of the foreign copper purchased by F. E. A. was at a cost in excess of 12 cents a pound. Dr. Bateman also stated that 80 percent of purchases is delivered at 11.75 cents a pound and 20 percent at above ceiling prices of the Office of Price Administration, making the current average price for all imported copper less than 12.5 cents a pound. At the time he talked the Government's foreign procurement, combined with private purchases, was at an annual rate of over 1,000,000

for copper. In discussing problems raised by wartime foreign procurement, he said:

Statements have been made publicly that vast sums were loaned to foreign countries for mineral developments. I should like to correct this. No loans as such were made by the Metals Reserve Company or the Foreign Economic Administration for foreign mineral development. In certain cases, however, credits against future delivery were made to permit development and plant expansion. In a few cases, the Defense Plant Corporation built new plants or plant expansion. Most of the foreign mineral financing or plant expansion was made by the producing companies. The hazards, uncertainties, and high cost of such contracts necessitated that certain risks be undertaken by the Government, and such contracts were made f. o. b. foreign ports.

POSSIBLE NEED FOR INTERNATIONAL COOPERATION

The future for copper from an international standpoint has been considered alarming in some quarters. Under the stimulus of gigantic war demand, world production had grown to roughly 3,000,000 short tons annually. Prewar (1928-37) rates averaged 1,700,000 tons. Thus an excess capacity of 1,300,000 tons appeared to exist unless postwar consumption rates were established at higher than prewar levels. Moreover, Chile, which made the greatest tonnage gain among exporting nations became divorced from accustomed European markets during the war and faced greater competition for them in the future. The United States began to take almost all of Chile's output in 1941. When the war is over the United States will be able to supply all of its consumption requirements provided the excise tax is continued, and particularly if consumption rates recede to prewar levels. Canada's increased production appears to be without an assured market, and production from Rhodesia and Belgian Congo appear to face reduced markets. Costs of production in Chile have risen during the war until they are no longer as favorable competitively as before. Production in Canada is largely byproduct, and this condition is a strong competitive factor. Some preference in filling British Empire needs may be accorded Rhodesia because it is a colonial producer and operates on a sterling base. Belgian Congo, which would compete for the same markets as the other large producers outside of the United States, has large, high-grade reserves and an undoubted advantage over some others in the matter of costs. Except for the United States, there are no present important copper-consuming centers outside of Europe, U. S. S. R., and Japan. Nationals of the United States are in the dual position of wanting the domestic market protected and of having interest in cooperative beneficial action in the international market because of their control of all large copper mines in Chile, Peru, and Mexico and of their large investments in Rhodesian mines. There was much speculation during the year, particularly in the latter part, as to possibilities for handling the delicate problems presented by the foregoing conditions because the adverse attitude of the United States Government toward cartels was well-known. Unless unexpectedly high rates of consumption prevail in the world after the war, a reduction in production appears inevitable. Whether such reduction results from competition or through cooperative action was a matter for conjecture at the end of 1944. The Metal Bulletin (London) of December 22 repeated a prediction that marketing problems facing primary copper producers as war consumption diminished would lead eventually to an attempt to arrange a control scheme under Government auspices.

RESERVES

Pehrson ¹ has presented the following analysis in regard to United States copper reserves:

Copper reserves as of 1944 have been estimated by Ralph S. Cannon (Geological Survey) and McHenry Mosier (Bureau of Mines) at 20,000,000 tons of recoverable metal under prevailing conditions. Since they include some reserves available only at premium prices they may be considered as a generous appraisal of commercial reserves under normal conditions. A quarter of the tonnage is classed as inferred. It is estimated that production could be maintained at the rate of 1,000,000 tons per year for nearly 10 years, following which would come a gradual decline to exhaustion. Submarginal resources have been estimated at 10,000,000 tons of copper contained in 1.25 billion tons of material.

INVESTIGATIONS OF THE GEOLOGICAL SURVEY AND THE BUREAU OF MINES

Geologic investigations of copper resources were actively continued by the Geological Survey throughout 1944. Copper deposits in Alaska and Mexico were studied, as well as in Arizona, California, Colorado, Idaho, Michigan, Montana, New Mexico, North Carolina, Texas, Virginia, and Wisconsin.

A number of domestic copper deposits were examined in 1944 at the request of war agencies, and several studies were conducted in conjunction with exploration projects of the Bureau of Mines. Rather comprehensive investigations of the Bagdad, Castle Dome, and San Manuel porphyry copper deposits in Arizona and at active mines on the Keweenaw Peninsula of Michigan and the foothill copper belt of California were continued throughout the year. Results of several completed studies were made available to the public in preliminary form. Preliminary geologic maps of the Orange County, Vt., copper district, and of the Reward area, Casa Grande district, Pinal County, Ariz., were released for public distribution. Preliminary reports on studies of the Orange County, Vt., copper district, and the Empire mine near Mackay, Custer County, Idaho, were placed in open files.

In southeastern Alaska the Geological Survey investigated the iron-copper deposits of the Mount Andrew area and the Tolstoi Mountain area on Kasaan Peninsula, the copper-bearing zinc deposits at Tracy Arm on the mainland, and the copper-bearing iron deposits of Jumbo Basin. The copper-bearing molybdenum deposits at Orange Hill in the Copper River region also were studied.

In Mexico the Geological Survey investigated copper deposits at La Dicha in Guerrero and at Oropeo in Michoacan during 1944 under the auspices of the United States Department of State.

The Bureau of Mines continued its copper-exploration projects in 1944, and war minerals reports on the following areas were issued for limited distribution.

- 158. Western Nevada Copper Co., Lyon County, Nev., January 1944.
- 159. Moffet-Johnston Property, Madison County, Mont., February 1944.
- 160. Ore Knob Mine, Ashe County, N. C. (Supplement to No. 61), February 1944.
- 190. Majuba Hill Mine, Pershing County, Nev., May 1944.
- 217. Toncræ-Howard Properties, Floyd County, Va., August 1944.
- 228. Eureka-Union (Vermont Copper Co.), Orange County, Vt., August 1944.
- 236. Green Mountain Copper Mine, Sanders County, Mont., September 1944.
- 246. Boston Consolidated Mine, Salt Lake County, Utah (Supplement to No. 127), October 1944.

- 257. Ely Mine, Orange County, Vt. (Supplement to No. 6), October 1944.
- 258. Copper Nugget Placer, Jefferson County, Mont., November 1944.
- 259. Empire Mine, Mackay, Custer County, Idaho (Supplement to No. 68), November 1944.
- 260. Old Reliable Mine, Pinal County, Ariz., November 1944.
- 261. Virginia District, Halifax County, Va., Person and Granville Counties, N. C., November 1944.
- 262. Atwood Group, Lordsburg District, Hidalgo County, N. Mex. (Supplement to No. 25), November 1944.
- 263. Copper King Mine, Taos County, N. Mex., November 1944.
- 264. Rambler Mine, Albany County, Wyo. (Supplement to No. 17), November 1944.
- 265. Colorado Copper Co. Deposits, Montrose County, Colo., November 1944.
- 266. Suggested Mining Methods at Christmas Mine, Gila County, Ariz., December 1944.

POSTWAR OUTLOOK

Opinion is virtually unanimous that the war will be followed by a period of great industrial activity in the United States and that a similar condition will develop abroad where finances are available or credits obtainable. In the United States this activity will characterize the period when pent-up demands for automobiles, refrigerators, washing machines, and other items are being filled, and abroad it will come when reconstruction and rehabilitation are in progress. During this era copper, always a good index of industrial activity, will be in large demand. The possibility that, after the war, substitute materials will replace copper in large or small degree was discussed in the report of this series for 1943, and the conclusion was reached that the relationship between postwar levels of consumption of copper and general industrial activity will be similar to the prewar relationship.

R. L. Wilcox,² chief, Metals Branch Conservation Division, War Production Board, commented that some metals in relatively ample supply are in a very advantageous position to develop and possibly to enter postwar markets which would normally employ another metal the supply of which had been inadequate. In connection with the question as to whether metals in insufficient supply would regain their normal uses, he said:

This is a difficult question to answer—undoubtedly some normal uses of certain metals will never be regained—but based on almost 3 years experience in the War Production Board on problems of substitution of one metal for another, it would appear that contrary to popular belief the normal or prewar use position or standing of our common metals will continue after the war with little real change.

Ingalls³ discussed the possible level of consumption in the United States after the war as follows:

The total of these estimates, omitting shipbuilding, is 1,265,000 tons, which I think may be an understatement rather than an overstatement. Estimating that two thirds of this will be supplied with new copper, which is a little higher than the ratio in 1937, the indicated tonnage is 843,000 or, say, 850,000. The total of 1,265,000 for new copper plus old compares with 1,129,000 in 1937 which was our largest prewar year since 1930. The total of 1,129,000 (which remains after deduction of manufactures for export) figures at 17.5 pounds per caput. A consumption of 1,265,000 tons would be 18 pounds per caput of the expected population of 140 million at the middle of 1945. A gain of that order would not be in any way out of harmony with an idea of the increases under the heads of building, motor vehicles, communications, and otherwise that are required to supply deficiencies.

¹ Wilcox, R. L., *The Battle of Tempo R*: Min. Cong. Jour., vol. 30, No. 12, December 1944, p. 42.

² Ingalls, W. R., *What for Copper After the War?*: Min. and Met., vol. 25, No. 453, September 1944, pp. 47-49.

Regarding substitution he concluded:

In general copper and the several copper alloys are valued for the uses to which they are especially adapted and for that reason have resisted substitutions for cheaper substances.

Thus, the two writers quoted agree that substitution of other materials for copper will not be serious after the war; in fact, Ingalls thinks that postwar consumption will exceed that for 1937, when consumption was higher than at any time since 1930.

The foregoing discussion fortifies the opinions concerning the postwar outlook in the chapter on Copper of Minerals Yearbook, 1943, but another year of postponed civilian needs has been added. The 1943 report, however, stated that two political factors would have a sharp bearing on the postwar demand for newly mined copper, that is, the Government attitude toward stock-piling refined metal, intermediate war materials, scrap returned from battlefields, and scrap from obsolete equipment of all kinds, and the Government attitude toward permitting entry into the country of foreign crude, refined, and fabricated copper. The first of the two questions was settled only for 1 year by the passage of the Surplus Property Act, already described. The answer to the second question is tied in with continuation of the excise tax on copper after the war and with Government action in regard to the Reciprocal Trade Agreements Act through which the copper tax may be reduced 50 percent; that is, the present level of 4 cents a pound could be cut to 2 cents.

The restraining influence of the Office of Price Administration on price increases in general has not prevented them altogether; as a consequence, costs of producing copper have increased during the war. Moreover, because of emphasis on high production rates a considerable quantity of the more cheaply mined copper has been removed from the ground. Labor shortage, too, has impeded development, and this condition points to higher costs in the future. The foregoing factors indicate that higher copper prices may be needed in the postwar era to bring out enough copper for the anticipated domestic demand.

From an international standpoint a perplexing problem results from the fact that world production capacities are considerably above even the most optimistic ideas concerning postwar world-consumption levels. This problem was discussed under Possible Need for International Cooperation.

DOMESTIC PRODUCTION

Statistics on copper production may be compiled upon a mine, smelter, or refinery basis. Mine data are most accurate for showing the geographic distribution of production; smelter figures are better for showing the actual recovery of metal and fairly accurate for showing the source of production; and refinery statistics give precise information regarding metal recovery but indicate only in a general way the source of crude materials treated. The chapter on Copper in Mineral Resources of the United States, 1930, part 1, discusses the differences among the three sets of figures.

For detailed information by States, districts, and mines, the reader is referred to the various State chapters on gold, silver, copper, lead, and zinc.

Copper produced from domestic ores, as reported by mines, smelters, and refineries, 1940-44, in short tons

Year	Mine	Smelter	Refinery
1940	878,086	909,084	927,239
1941	958,149	966,072	975,408
1942	1,080,061	1,087,991	1,064,792
1943	1,090,818	1,092,939	1,082,079
1944	972,549	1,003,379	973,852

PRIMARY COPPER

Smelter production.—The recovery of copper by smelters in the United States from ores of domestic origin totaled 1,003,379 short tons in 1944, a decline of 8 percent from the total of 1,092,939 tons for 1943. Domestic smelter output constituted 51 percent of the world production during 1925-29 but dropped sharply in the succeeding years until 1934, when it was only 17 percent. From 1936 to 1940 it fluctuated between 25 and 32 percent, and in 1942-44 it is believed to have been close to 35 percent.

The figures for smelter production are based upon confidential returns from all smelters handling copper-bearing materials produced in the United States. For Michigan the sum of furnace-refined copper and copper cast into anodes for electrolytic refining is included. The figures for blister represent the fine-copper content. Some casting and electrolytic copper produced direct from ore or matte is included in the smelter production. Metallic and cement copper recovered by leaching is included in smelter production.

The precise quantity, in pounds, of copper produced by smelters in the United States and its value are shown by years for 1845-1930 in the Copper chapter of Mineral Resources of the United States, 1930, part 1.

Copper produced in the United States from domestic ores, 1940-44, by States

(Smelter output, in short tons fine)

Total, 1845-1944.....	31,648,859	9,231,510,000

¹ Excludes bonus payments of Metals Reserve Company.

Mine production.—The figures for mine production are based upon reports supplied to the Bureau of Mines by all domestic mines that produce copper. Details of the method of collecting the statistics and reasons for the discrepancy between mine-, smelter-, and refinery-production figures are given in the Copper chapter of Mineral Resources of the United States, 1930, part 1.

Mine production is more accurate than either refinery or smelter production for showing the distribution of domestic output by States and districts. It also indicates the production by calendar years more exactly, because additional time is required for smelting and refining. Mine production in 1944 was 972,549 tons—a decrease of 11 percent from that in 1943 but 10 percent above the average for 1925-29.

Production by States and districts.—The following tables show mine and smelter production, by States, for 1943 and 1944 and mine output, by districts, for 1940-44. Arizona, with 37 percent, produced the largest share of the total in 1944, as for many previous years. Utah, which has been gaining during the war period, was close behind the premier State with a 30-percent share. Montana, which ranked third, produced less than one-third of Arizona's total and contributed 12 percent of the total for the United States. Together the three States contributed nearly 79 percent of the country's total and with the next three States in rank (New Mexico, Nevada, and Michigan), 96 percent. Production in all of the important copper-producing States decreased in 1944, and the declining movement was characteristic of operations in most States. Noteworthy exceptions to the general trend were California, Missouri, and Vermont, where Government aid in opening or expanding production brought positive results. Comparison of present production with that of the past century focuses attention on Utah's sharp rise, the leveling off of production in Arizona, and the large drops in Michigan and Montana. In 1944 New Mexico produced close to double the percentage for 1845-1944, and Nevada likewise showed a gain though in smaller proportion.

The Bingham district, Utah, ranked first among the copper-producing districts of the world in 1944; this district had held the preeminent position among United States copper districts since 1936. Production in the Bingham district was 2.4 times as large as in the Butte district, Mont., normally the second ranking area. In total output from the beginning of operations Butte easily outranks all other districts, having produced well over 6 million tons at the end of 1944. The Globe-Miami district had seemed fairly well established as the third ranking district a few years ago, but sharp gains in production at the Morenci mine caused the Morenci district to rise to third position in 1944.

Copper produced in the United States according to smelter and mine returns, by States, 1943-44, and 1845-1944, in short tons

Quantity and estimated recoverable content of copper-bearing ores.—The following tables list the quantity and estimated recoverable copper content of the ore produced by mines in the United States in 1943; complete details for 1944 are not yet available. Of the total copper produced from copper ores in the United States during 1943, 88 percent was obtained from ores concentrated before smelting, 8 percent from direct smelting ores, and 4 percent from ore treated by straight leaching. The percentages for 1943 compared with 87 percent obtained from concentrated ore, 9 percent from direct smelting ores, and 4 percent by straight leaching in 1942.

Close agreement between the output as reported by smelters and the recoverable quantity as reported by mines indicates that the estimated recoverable tenor is close to the actual recovery. Classification of some of the complex western ores is difficult and more or less arbitrary. "Copper ores" include not only those that contain 2.5 percent or more copper but also those that contain less than this percentage if they are valuable chiefly for copper. Mines report considerable copper from ores mined primarily for other metals. These include siliceous gold and silver ores, lead and zinc ores, and pyritic ores.

Copper ore, old tailings, etc., sold or treated in the United States in 1943, with copper, gold, and silver content in terms of recovered metals

¹ Includes old tailings, etc.

Refinery production.—The refinery output of copper in the United States in 1944 was made by 11 plants; 7 of these employed the electrolytic method only, 2 the furnace process on Lake Superior copper, 1 the furnace process on western ores, and 1 both the electrolytic and the furnace methods.

Five large electrolytic refineries are on the Atlantic seaboard, three Lake refineries on the Great Lakes, and three electrolytic refineries west of the Great Lakes—one at Great Falls, Mont.; one at Tacoma, Wash.; and one at El Paso, Tex. In 1942 fire-refined copper was produced for the first time at the Hurley, N. Mex., plant of the Kennecott Copper Corp., and virtually all of the plant output was treated by this method in 1944. The El Paso plant of the Phelps Dodge Refining Corp. produced furnace refined copper in addition to the usual electrolytic grade. Of the plants specified above, the Lake refinery of the Quincy Mining Co. has been idle since 1933.

In addition to the foregoing plants, that at Inspiration, Ariz., is equipped to make electrolytically refined copper direct from the liquor obtained from leaching; this copper is shipped as cathodes to other refineries, where it is melted and cast into merchant shapes.

The 13 plants indicated constitute what commonly are termed "regular refineries." Of these plants, 8 employ the electrolytic process, 4 the furnace process, and 1 both methods. The electrolytic plants have a rated capacity of 1,595,000 tons of refined copper a year. As they produced 1,160,000 tons in 1944, this part of the industry was operated at 73 percent of capacity.

The following tables show the production of refined copper at regular refining plants, classified according to source, grade, and form in which cast.

¹ The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation at this stage of manufacture is not possible.

² Some copper from Michigan is electrolytically refined at eastern refineries and is included as electrolytic copper.

³ Data include copper imported for immediate consumption plus material entering country under bond.

⁴ Includes some secondary Lake copper.

Copper cast in forms in the United States, 1943-44

Form	1943		1944	
	Short tons	Percent	Short tons	Percent
Wire bars.....	473,500	31.53	493,000	37.2
Cathodes.....	503,000	33.50	358,000	27.5
Ingot.....	265,000	17.65	229,000	17.5
Cakes.....	145,500	9.69	104,000	7.9
Other forms.....	114,500	7.63	124,000	9.5
	1,501,500	100.00	1,308,000	100.0

In addition to the regular refineries, numerous plants throughout the country operate on scrap exclusively, producing metallic copper and a great variety of alloys. The output of these plants is not included in the statements of refined-copper production in the preceding tables but is included in the following statement on secondary-copper production.

Copper sulfate.—The production of hydrous copper sulfate or blue vitriol by copper refineries in the United States was 33,100 short tons containing a copper content of 8,269 tons in 1944 compared with 30,700 tons containing 7,667 tons in 1943. The output of copper sulfate by refineries other than the regular primary refineries totaled 69,500 tons with a reported content of 17,377 tons in 1944 compared with 58,400 tons containing 14,597 tons of copper in 1943. Producers held 14,300 tons of copper sulfate at the beginning of 1944, total production was 102,600 tons, and shipments amounted to 97,900 tons. Some small purchases were made during the year, and producers used an amount equivalent to 4 percent of shipments. Inventories at the year end were 10,300 tons.

The Requirements Committee of the Chemicals Bureau (War Production Board) approved the program shown later for distribution of copper sulfate in the 1944-45 agricultural year. The period covered was the 4 quarters beginning October 1, 1944, for everything except copper sulfate destined to areas liberated from Nazi domination and to the first 3 quarters only for the last-named item. The program applied to the following quantities:

	Pounds
U. S. Military Government (for United Nations Relief and Rehabilitation Administration in liberated areas).....	18, 337, 000
Food Administration.....	100, 000, 000
Economic Administration (banana, mining, and other uses in countries that come under this organization).....	60, 000, 000
Other.....	3, 000, 000
Total purposes.....	75, 000, 000

The foregoing distribution was contingent on the ability of the industry to accelerate production to meet the large requirements and on the allocation of adequate raw materials by the Copper Division of the War Production Board.

SECONDARY COPPER

Secondary copper includes material recovered from remelting old copper and copper scrap and from the treatment of copper alloys or alloys treated without separation of the copper. The following table summarizes the production of secondary copper during 1940-44. Further details appear in the chapter on Secondary Metals—Non-ferrous.

Secondary copper produced in the United States, 1940-44, in short tons

	1940	1941	1942	1943	1944
Copper recovered as unalloyed copper.....	170, 839	135, 869	114, 647	137, 883	102, 135
Copper recovered in alloys.....	1 361, 207	1 590, 527	1 813, 108	1 948, 164	1 848, 807
Total secondary copper.....	532, 046	726, 396	927, 755	1, 086, 047	950, 942
From new scrap.....	198, 156	313, 697	500, 633	658, 526	494, 232
From old scrap.....	333, 890	412, 699	427, 122	427, 521	456, 710
Percentage of domestic mine output.....	61	76	86	100	98

Other copper in chemicals, as follows: 1940, 9,431 tons; 1941, 9,804; 1942, 17,455; 1943, 13,019; 1944, 13,357

CONSUMPTION

The following table gives figures on apparent consumption of copper in the United States. In estimating apparent consumption it has been assumed that copper used in the manufacture of primary fabrications of copper is consumed. It is likely that statistics compiled upon a different basis (for example, by taking consumption as including or excluding copper made into automobiles, electrical equipment, ships, and other items) would show very different results. Much copper leaves the country as primary fabrications and considerably more in manufactured products containing copper. During the war large quantities of copper exported for military use were not accounted for in the foreign trade statistics. Likewise scrap or other materials imported on returning transport vessels were not listed in import figures. Actual consumption data may be compiled at many points in the industrial process. The method of calculating the quantity of copper available for consumption is shown in the following table. It should be noted that exports and stocks include some refined secondary copper that cannot be determined separately and also that actual consumption of new copper would differ from the figures shown in the table by the changes in the consumers' stocks.

New refined copper withdrawn from total year's supply on domestic account, 1940-44, in short tons

	1940	1941	1942	1943	1944
Total supply of new copper.....	1,381,893	1,742,303	1,815,997	1,782,025	1,713,591

Withdrawn on domestic account.....	1,008,785	1,641,550	1,678,091	1,621,666	1,632,720

¹ Includes refined copper in ingots, bars, rods, or other forms.

Excludes refined copper in rods.

STOCKS

The following table gives domestic stocks of copper as reported by primary smelting and refining plants. Stocks of blister and anode copper in transit from smelters to refineries are included under blister copper.

Stocks of copper at primary smelting and refining plants in the United States at end of year, 1940-44, in short tons

Year	Refined copper	Blister and materials in process of refining ¹	Year	Refined copper	Blister and materials in process of refining ¹
1940.....	91,500	243,000	1943.....	68,500	241,000
1941.....	77,500	240,000	1944.....	81,000	311,000
1942.....	84,000	235,500			

¹ Includes copper in transit from smelters in the United States to refineries therein.

inventories of copper available for war and essential civilian requirements increased in 1944, although stocks in all hands did not. Refined metal held by producers rose 18 percent, and blister and anodes in process of refining increased 27 percent. Stocks of refined copper in the hands of the Metals Reserve Company advanced sharply during the year. Totals for 1944 may not be stated as yet. At the end of 1943, 166,400 tons of electrolytic copper and 57,681 tons of fire-refined metal were on hand. Metals Reserve Company inventories are upon an ownership basis and, therefore, duplicate in part stocks reported by the refineries, which are on a plant basis. The precise amount of the duplication is not known, but it is believed to have approximated 14 percent of the Metals Reserve total at the end of 1944. Although fabricators' stocks declined both in 1943 and 1944 the general condition of these concerns improved materially during the year period. Stocks of refined copper, of material in process, and of primary fabricated shapes decreased from 414,668 tons at the end of 1943 to 334,017 tons at the end of 1944, or 19 percent. Meanwhile unfilled orders declined from 613,005 to 285,654 tons, respectively, or 53 percent, and the excess of stocks over orders booked, though still a considerable quantity, declined from -403,403 to -187,259 tons. At their all-time peak, unfilled fabricators' sales to customers totaled 689,177 tons in June 30, 1942. Thus, unfilled sales at the end of 1944 amounted to more than one-fourth of the peak tonnage for June 1942.

Stocks of copper in fabricators' hands at end of year, 1940-44, in short tons

	Stocks of refined copper	Unfilled purchases of refined copper from producers	Working stocks	Unfilled sales to customers	Excess stocks over orders booked
1940	1,713,900				
1941	1,782,000				
1942	1,782,000				
1943	414,668	326,269	240,740	414,892	10,013
1944	334,017	241,335	291,515	547,468	-304,675
		135,481	340,547	613,005	-403,403
		90,807	299,796	465,258	-320,299
		53,538	289,160	285,654	-187,259

Includes process metal and primary fabricated shapes. Also includes small quantities of refined metal at refineries for fabricators' account.

Figures compiled by the Copper Institute show that domestic sales of refined duty-free copper increased from 52,121 tons at the end of 1943 to 66,780 tons at the end of 1944. Inventory data of the Copper Institute and the Bureau of Mines are on different bases and, as a result, never agree. Under usual conditions the differences are in part to the somewhat different coverage and in part to an arbitrary but permissible method used by the Copper Institute in designating the copper as domestic or foreign metal. Owing to the fact that copper entering the United States since the end of 1941, as much as that imported in 1941, has been for the account of the Metals Reserve Company, stock data of the Copper Institute and the Bureau of Mines have been in closer agreement than during the period preceding the start of Metals Reserve Company purchases.

PRICES

Reports to the Bureau of Mines from copper-selling agencies indicate that 1,060,000 short tons of copper were delivered to domestic and foreign purchasers (excluding deliveries of foreign copper to the Metals Reserve Company) in 1944 at an average price (f. o. b. refinery)

of 11.8 cents a pound, unchanged from 1943, 1942, and 1941. The averages for 1942-44 exclude bonuses paid for overquota outputs individual mines, which were first applicable to February (194 tonnages). Complete details covering bonus payments since they began were released recently in a study made by the Office of Price Administration. The following table was compiled from the report.

Salient statistics covering bonus payments¹ of the Government from the inception of such payments (February 1, 1942) through 1944

Source: For 1940, 1941, 1942, 1943, 1944, London Metal Exchange dealings suspended for duration of war.

Price limitations, placed by the Office of Price Administration on electrolytic and casting copper, were described in earlier parts of this series. There were no changes in the ceilings in 1944. The bonus-payment plan, also described in earlier reports, permitted payment of 5 cents a pound above the ceiling price to most producers and to other producers for production from high-grade sections of mines. Special bonuses were permitted where the ceiling price plus the 5-cent bonus failed to cover mine costs, and, as shown by the foregoing table, such payments in some instances amounted as much as 27 cents, including the ceiling price. Bonuses were paid on 25 percent of production in 1944 compared with 23 percent in 1943 and 11 percent in 1942. Special bonuses were paid on less than 3 percent of total output in 1944, which was the year of greatest distribution for this purpose. Payments under special Metals Reserve Company contracts likewise covered less than 3 percent of production and also reached a peak in that year nonetheless. To official maximum prices, delivered to consumers' plants, have been added in the London market since December 18, 1939:

FOREIGN TRADE³

Before the war United States imports and exports of copper constituted a well-balanced trade through which the smelting, refining, and manufacturing facilities of this country were used to treat foreign materials and to return refined copper and manufactures of copper abroad. The war has caused wide disruption of foreign trade in general and has disturbed the prewar flow of copper exports. Not only did the United States require all of the copper imported after this country's entry into the war, but most of the countries to which copper was shipped formerly were no longer appro-

Source: Imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Department of Commerce.

appropriate markets for exports of metal from domestic plants. The general expansion in war requirements in the United States led to successive high import records in 1941 and 1942, and following a drop of 6 percent in 1943 to a new peak in 1944. Time and shipping shortages led the United States Government to give purchase and shipping priority to the highest class of copper—refined—and this class reached successive peaks in 1941 and in every year thereafter. Refined metal contributed 63 and blister 23 percent of total imports of unmanufactured copper in 1944 contrasted with 5 and 73 percent, respectively in 1939. Chile has been the chief source of imports of refined copper since the war began, as during many previous years. Noteworthy increments from Canada began in August 1944 coincidental with the period of smaller requirements for the United Kingdom. All classes except refined were received in smaller quantities in 1944 than in 1943. Chile and other Western Hemisphere sources supplied most of the blister copper, concentrates, and ore entered in 1944, as in 1943, while the Belgian Congo contributed most of the regulus and black or cast copper in both years.

The export movement since the war began has been distinguished by the sharp falling off in shipments of refined metal, formerly by the largest export class, and by the proportionately greater rise in shipments of insulated wire and cable. Exports went largely to Japan and to certain European countries—Belgium, France, Germany, Italy, Sweden, and the United Kingdom—as has been pointed out in previous reports of this series. Out of the foregoing list, it has been expedient to keep only the United Kingdom as a customer since the war began. The U. S. S. R. joined the United Kingdom as one of two principal destinations of exports of refined copper and of primary fabricated copper shapes. One of the outstanding records of the war insofar as copper is concerned, has been the enormous rise in exports of insulated wire and cable, the use of which plays such an important part in numerous war activities.

IMPORTS

The shift in emphasis from unrefined to refined copper imports since the prewar period has been striking, and this movement was continued in 1944. Receipts of refined copper established successive annual peaks beginning in 1941 (when the total was nearly four times the previous record for 1931, the year before the imposition of the 4-cent excise tax on copper), the total for 1944 being 22 percent above 1943. It seems worthwhile to repeat the comparisons given in the 1943 report of this series and to add thereto. Imports of refined made up 4 percent of the total imports of unmanufactured copper in the period 1935-53 percent in 1942, 57 percent in 1943, and 63 percent in 1944. accentuating the highest grade, shipping space was utilized to the advantage, and time was saved in delivering metal to the consuming industry. The refined metal entered since the excise tax was imposed came almost entirely from Chile until midyear 1944. Then the conditions of larger supply in the United Kingdom resulted in the shipment of increasing quantities from Canada to the United States. Imports of refined copper from Canada amounted to less than 1 percent of the total in the first 6 months of 1944 but made up 15 percent in the latter half of the year. The proportion from Canada was expected to grow in 1945. Receipts of all other classes of unma-

Imports declined in 1944 as compared with 1943: Ore decreased 18 percent; concentrates, 3 percent; regulus, black or coarse cement-copper, 10 percent; and unrefined black blister converter copper, 5 percent. Unrefined black blister is the most part of the unrefined grades, and imports of this class came mainly from Chile, Mexico, Peru, and Belgian Congo, as in 1943, the last two from the two South American countries showing increases. Black or coarse copper, comes chiefly from the Belgian Congo and receipts from that country declined in 1944. Western Hemisphere countries supplied most of the concentrates and ores in 1944 as in 1943, with Canada leading in the concentrates and Chile ahead in the ore class.

EXPORTS

Refined copper dominated the export group, usually by a very substantial margin, from before 1900 until displaced by the wire classification in 1944. The weight of bare and insulated wire in 1944 was $2\frac{1}{4}$ times as large as refined copper so that even on a copper content basis wire largely exceeded the refined class. The share of war gains in exports of insulated wire and cable have been pointed out previously. The total for this class for 1942 was 119 percent above 1941, and 1943 was 54 percent higher than 1942; the 1944 total rose 56 percent above 1943. Attention has also been called in previous reports to the fact that exports of this class of wire furnish a guide either to the battle contestants or the battle areas. This condition continued in 1944, when the U. S. S. R. received 63 percent of the total, the United Kingdom 16 percent, and quantities of over 1,000 tons each went to India, New Zealand, and Australia. Two countries that received expanded quantities in 1943, Egypt and Algeria, were passed by the war in that year, and they dropped from the list of important export destinations of wire.

The size and destinations of exports of refined copper have changed drastically since before the war. In 1944 exports of this class dropped 61 percent from 1943 and amounted to only 22 percent of the average annual rate for 1935-39. Shipments went chiefly to the United Kingdom, the U. S. S. R., and Mexico in 1944, whereas Japan received the largest share of exports in 3 of the years 1935-39 and was a close second in the other 2; the other subsequent enemies (Germany and Italy) received large quantities throughout the period (Germany was seventh in 1939 and Italy was sixth in 1938, but otherwise they both ranked fifth or higher as export destinations). Moreover, Germany could have received much of the copper that showed in the statistics as being destined to neighboring countries such as Belgium, Netherlands, and Sweden, which were indicated to have received substantial quantities in the prewar period. The United Kingdom for many years has been one of the chief takers of copper sent from the United States, whereas the U. S. S. R. did not become an important buyer until 1939.

The U. S. S. R. also dominated exports of primary fabricated products other than insulated wire in 1944 as in 1943. These classes, however, did not account for important tonnages in either year.

WORLD PRODUCTION

State data covering world production of copper since the outbreak of World War II have been unobtainable, but enough information is at hand to indicate that production has averaged roughly 40 short tons for the 3 years ended in 1944. Previous reports have stressed the fact that the United Nations and the Axis held disproportionate shares of the world total and that production strongly favored the former group. The 1943 Copper Report stated that the Axis had access to not much more than 300,000 tons, or possibly as little as 10 percent but surely not more than 24 percent of the total. In 1944 the adverse position of the Axis was worse. Germany's chief source of newly mined copper in 1940 had been the Bor mine in Yugoslavia, and supplies from this source were cut off by Germany's military reverses in the latter part of 1944. At about the same time access to Philippines copper was denied the Japanese, also because of military reverses.

REVIEW BY COUNTRIES

Australia.—Production at Australian mines is reported to have reached the high total of 31,300 metric tons in 1944. Efforts of the Commonwealth Government to increase production were relaxed in 1944 for a time early in the year it appeared that the recently opened copper production by the Mount Isa Mines, Ltd., Queensland, would be without a domestic market. Under war stimulation the mine had become the largest copper producer in Australia. Later the Government assured the company an outlet until the end of 1944, the matter being subject to review at that time. Mount Isa's ore reserves were estimated at 2,442,000 tons, assaying 3.2 percent copper. Mount Morgan, Ltd., in the same State, did not have a disposal problem but was handicapped seriously by insufficient labor. Operations at Mount Chalmers mine, 36 miles northeast of Mount Morgan, were continued by Mount Morgan, Ltd., in the first part of 1944 at least. An approximate reserve of 400,000 tons of copper ore prompted reopening of this mine. Mount Lyell Mining & Railway Co., Ltd., Tasmania, was regularly the largest producer in Australia before the war. Labor problems beset this company also in 1944, and production fell. Reserves for the fiscal year ended September 30 were estimated at 12,882,000 tons having an average copper content of 1.14 percent.

Bolivia.—Production amounted to 6,170 metric tons in 1944 compared with 6,011 tons in 1943. The Metals Reserve Company contract to purchase copper in Bolivia expired on March 1, but the Banco Boliviano purchased the outputs of small miners during that month. Such as the American Smelting & Refining Co., by far the largest purchaser in the country, was not a party to the Metals Reserve Company contract, the effect of its expiration was expected to be slight.

World mine and smelter production of copper, 1939-44, in metric tons

	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	------	--------

Canada.—Canadian mine production has dropped in each year since the peak rate was reached in 1940; the total for 1944 was 273,972 short tons compared with 287,595 tons in 1943, 301,831 in 1942, 321,658 in 1941 and 327,797 in 1940. Labor shortages were the principal cause of the declines. Production of refined copper made a slight gain in 1944, or from 251,495 tons in 1943 to 251,871 tons. The refined copper is produced at the Copper Cliff plant of the International Nickel Co. of Canada, Ltd., and the Montreal East plant of Noranda Mines Ltd. The chief Canadian mines contracted with the British Government at the beginning of the war for most of their output. These contracts were terminated on January 31, 1945, but producers' fears that their copper would lack a market proved without immediate foundation, at least, because of the continuing demand for enormous quantities of copper in the United States. Canadian copper producers appear to be in a favorable position to compete in postwar markets. Most of the copper produced in Canada comes from ores that have high values in other metals, such as nickel-copper and zinc-copper ores. Because of this condition the copper content does not need to carry its share of the costs of production. Mine production, by Provinces, is shown in the accompanying table.

Copper produced (mine output) in Canada, 1940-44, by Provinces, in short tons

Province	1940	1941	1942	1943	1944 (preliminary)
British Columbia	38,871	33,164	25,008	21,111	18,000
Manitoba	37,634	33,509	23,798	19,008	21,900
Ontario	173,966	166,915	154,141	138,920	141,800
Quebec	67,083	71,892	70,456	65,582	55,200
Saskatchewan	10,243	16,162	28,391	42,974	36,900
	327,797	321,658	301,831	287,595	273,972

¹ Includes Northwest Territories.

As usual, more than half of the Canadian production came from the nickel-copper mines of the Sudbury district, Ontario, and the International Nickel Co. of Canada, Ltd., was again the principal copper producer. This company's sales of copper in all forms, derived from company mines, amounted to 134,503 short tons in 1944, representing a small increase over the 132,744 tons in 1943. The Falconbridge Nickel Mines, Ltd., the other important producer in Ontario, hoisted 829,392 tons of ore in 1944 and treated 830,254 tons for the recovery of 6,383 tons of copper in matte. The company reported reserves at the end of 1944 to be 12,669,500 tons of ore, averaging 1.7 percent nickel and 0.93 percent copper, of which 7,995,500 tons were in the Falconbridge mine. Both companies complained of labor shortages in 1944.

Quebec ranks second as a copper-producing Province, but output in this area amounts regularly to less than half of that for Ontario. In 1944 the ratio was 1 : 2.6. Noranda Mines, Ltd., is the principal producer in Quebec. A total of 1,553,857 tons of ore was hoisted at the Horne mine in 1944. Ore and concentrates from the Horne mine totaling 703,153 tons, were smelted; and 28,290 tons of copper, 196,400 ounces of gold, and 508,126 ounces of silver were produced. Custom material totaling 345,285 tons also was smelted, and the total

gray and custom copper was 56,543 tons. Ore reserves above 1,355-foot level on January 1, 1945, totaled 5,266,000 tons averaging 2.88 percent copper and 15,997,000 tons containing 0.80 percent, some siliceous fluxing ore. The decline in ore reserves resulted in labor shortages that prevented the carrying on of adequate equipment. Operations at the property of the Normetal Mining Corporation, Ltd., were handicapped by the inadequacy of the power as well as by a labor shortage. Ore reserves, after 192,994 tons were treated in 1944, amounted to 1,380,000 tons. Waite Mines, Ltd., produced 20,500 tons of copper in 1944, the decrease from nearly 25,000 in 1943 being due mainly to the insufficient supply. Ore reserves for Waite Amulet and Amulet Dufault totaled approximately 3,000,000 tons at the end of 1944. Canadian Copper Refiners, Ltd., Montreal East, produced 103,000 tons of copper, 396,000 ounces of gold, and 3,380,000 ounces of silver. The company was constructing a new copper sulfate plant, which was expected to go into production before the middle of 1945. The company of the new plant was expected to take care of Canadian requirements for copper sulfate.

The copper produced in Manitoba and Saskatchewan comes regularly from the Flin Flon mine of the Hudson Bay Mining & Smelting Co., Ltd., and the Sherritt Gordon Mines, Ltd., and in 1944 the old Mandy shaft operated by Emergency Metals, Ltd.—a wholly owned subsidiary of the Hudson Bay company—contributed to the total output. At the Flin Flon mine 2,059,206 tons of ore were mined and milled, and 2,027,926 tons were milled. Ore and concentrates treated at the copper plant for company account yielded 43,241 tons of copper, 145,441 ounces of gold, and 2,017,443 ounces of silver. The most recent calculation of reserves for Flin Flon was for January 1943. At that time, 27,378,240 tons of ore averaging 2.59 percent copper were estimated to be in the ground. Sherritt Gordon Mines, Ltd., produced 12,271 tons of copper from 731,783 tons of ore mined and milled, compared with 13,480 tons of copper and 770,099 tons of zinc, respectively, for 1943. Production in 1944 also included 7,059 ounces of gold, 226,349 ounces of silver, and 23,910 tons of zinc concentrate. Total copper ore reserves at the end of 1944 were calculated to be 2,175,000 tons, averaging 2.59 percent copper and 2.20 percent zinc. Emergency Metals, Ltd., completed mining and milling all the down ore tributary to the old Mandy shaft, and this operation was terminated. The 62,227 tons of ore milled yielded 3,000 tons of copper, 5,322 tons of zinc, 3,501 ounces of gold, and 69,265 ounces of silver.

In British Columbia output of the mines of Granby Consolidated Mining & Power Co., Ltd., and the Britannia Mining & Smelting Co., Ltd., was under contract in 1944 to the United States Government. Labor shortages impeded operations in this area also.

Chile.—Activity at copper mines continued to be influenced by the heavy military requirements of the United States, to which virtually all of Chile's copper has been destined during World War II. Production in 1944 failed by a narrow margin to equal the high record rates for 1943 and 1942; 487,600 metric tons were produced compared with 509,378 and 489,158 tons, respectively. Smelter output totaled 490,441 tons in 1944 compared with 489,320 in 1943, both of which represented respective records. During the year the press reflected

the growing realization in Chile that the tremendous expansion in copper production due to the war and the inflationary effects on the national economy caused by the war presented serious problems in the postwar era; it also pointed out that the United States had a responsibility in the solution of the problems created. Copper is Chile's principal export. Costs of production have increased sharply during the war; and prewar markets, chiefly in Europe, will be susceptible to competition from other large copper-exporting countries after the war ends.

Since February 1, 1942, the smelters at Chagres and Natalgua have been operated by the U. S. Commercial Company (successor in this enterprise to the Metals Reserve Company) on a "cost-plus" basis. The contracts were scheduled to be terminated on January 31, 1943, but they were extended. For a number of years these smelters have depended for a major part of their smelter feed on ores and concentrates purchased from small operators. Some of the material shipped a considerable distance. The high cost of operation by small producers makes their continued production under competitive conditions problematical. Small producers have contributed a relatively unimportant percentage of total output.

The Chilean Government has imposed a number of different kinds of taxes on copper, and taxes have been increased during the war. A special tax calls for the payment after the price has reached 10 cents a pound at New York of the next 1½ cents to the Government, the following 1½ cents going to the producer.

Exports of electrolytic copper totaled 274,663 metric tons, of which 256,286 went to the United States, 16,235 to Brazil, and the remainder to other South American neighbors. Standard copper exports amounted to 217,209 tons, of which 214,121 went to the United States, 2,811 to Brazil, and the remainder to other South American countries. The quantities for electrolytic copper for 1943 were 245,117, 240,291, and 3,035 tons, respectively, and those for standard for 1943 were 211,057, 210,517, and 520, respectively. Ore exports totaled 20,811 tons in 1944, compared with 9,340 in 1943. Concentrates aggregated 6,937 and 3,879 tons, respectively. Total ore and concentrates for both years went to the United States.

Cyprus.—Copper mines and mining in Cyprus were described recently by Classen.⁵ Copper is the most important mineral of this island, and the present productive mines operate on sites once worked by the Phoenicians and the Romans. The Skouriotissa and Mavrovouni mines, in the Bay of Morphou, show extensive traces of Roman and Phoenician work and may be considered to have been the largest producers in those times. These mines were rediscovered in 1913 and began production in 1922, under ownership of an American company. The Skouriotissa ore body is a lenticular mass of cupriferous pyrite lying nearly horizontal, 1,900 feet long, 800 feet wide, and not more than 140 feet thick. A typical analysis shows about 2 percent copper. The Mavrovouni mine lies about 3 miles west of Skouriotissa, and the ore body resembles a pear in shape, standing on its base. The known ore body extends from about 300 feet above sea level to a depth of some 700 feet, but it has not been delimited. The ore is similar to

⁵ Classen, G. A., Impressions of Mining in Cyprus: Mining Jour. (London), vol. 224, No. 5719, Mar. 31, 1945, pp. 197-199. (Excerpts from a paper which appears in Bulletin 59 (1944) of the Kolar Gold Field Mining and Metallurgical Society.)

and the Skouriotissa, but its copper content is roughly three times as great, and the sulfur content is less. A flotation plant at the mine treats ore from both of the properties described. Other copper properties on Cyprus are the Limni mine in the northwest in the Bay of Chrysokhou, and the Kalavasso mines in the foothills east of Troodos, about 10 miles inland from the south coast. The Limni mine has never been operated; but the Kalavasso mines, which are reported to be extensive, began to produce in the months preceding World War II.

Northern Rhodesia.—Early in 1944 copper producers in Northern Rhodesia anticipated a production cut of 20 to 25 percent, due to the fact that copper supplies of the United Nations were less scarce at that time than for many previous months. The United Kingdom—then the chief destination of exports of Northern Rhodesia copper—after the beginning of the war—appeared to have sufficient supplies for all foreseeable requirements. Continuing large needs of other nations, however, made such a sharp cut inadvisable, and the plan to reduce production was modified. Production in 1944 amounted to about 225,000 tons, or 10 percent less than in 1943. In the latter part of the year copper producers in Northern Rhodesia, like those in Canada, looked forward to the termination early in 1945 of their war contracts with the British Government. The British Government informed the producing companies that contracts would not be renewed at the end of January 1945. The tremendous need of the military branches of the United States Government for matériel containing copper, however, postponed the problem somewhat, and late in 1944 the Governor of Rhodesia announced that production for at least the first quarter of 1945 would go to the United States. At a meeting of the delegates of the Chamber of Mines, the Officials' Association, and the Mine Workers Union at Lusaka, November 28, 1944, the Governor spoke concerning the future for copper, the principal industry of the country, and said, among other things, that Northern Rhodesia was not the world's cheapest producer owing in large part to the long, expensive rail haul to tidewater.

Again in 1944 copper companies were unable to publish any production figures for the fiscal year ended June 30. The May, June, and July 1944 issues of the Engineering and Mining Journal contained articles by Raymond Brooks on the discovery and development of Rhodesian copper properties.

Philippines.—The situation in regard to copper mining in the Philippines since the Japanese invasion was described by Bain.⁶ The following is quoted from his article:

The mining of copper and the making of brass are ancient Japanese industries. Not many years ago Japan stood next after the United States, and second in the world in copper production. Since then our own production has greatly increased, and Chile, Rhodesia, Canada and the Belgian Congo have risen to high rank as copper producers. Japan's production has also grown, but not nearly enough to enable her to maintain her old position as a producer.

In the years preceding the present war, Japan's domestic production stood at about 70,000 tons, which seemed to meet demands for consumption. Immediately before the war she purchased as much more abroad, mainly from the United States. In the most recent of those years she purchased enough ores and concentrates from Canada, Chile, and the Philippines to enable her furnaces to push production up to possibly 100,000 tons per year, much of which undoubtedly went into war storage. Imports were all cut off by the war. But early in 1942

⁶Bain, H. Foster, *Japan's Power of Resistance*: Foreign Affairs, vol. 22, No. 3, April 1944, p. 430.

the Japanese took possession of the Lepanto mine in the Philippines, from which they had previously been buying ore, and began to operate it. Incidentally, they found more than a million dollars' worth of ore and concentrate which had accumulated at the shore after shipments stopped. The mine had been producing at the rate of 11,000 tons of copper per year. The Japanese spared neither work nor expense to increase the output and have been very successful. They opened additional workings and were fortunate in finding richer ore. They moved in additional machinery from gold mines in Northern Luzon, improved shipping facilities from mine to shore, and, contrary to their policy elsewhere, raised wages and paid workers a premium for regularity in attendance. They are even reported to have issued gasoline to the large number of trucks plying between mine and dock. This is the only place in the Philippines where the issuance of gasoline for other than strictly military equipment has been reported.

These measures indicate that copper is one of the items most needed to carry out the Japanese program. The belief is reinforced by the news that has come of the widespread campaign for copper scrap under way in the Philippines and elsewhere and of the imposition, in the fall of 1943, of control measures over the use of copper wire. In addition, the Japanese are making efforts to develop mines out of small prospects in the central islands of the Philippines. All these various efforts seem to have been well-rewarded. From Lepanto alone by the end of 1943 copper was being drawn at a rate of about 36,000 tons per year, equal to half the normal output of the mines in Japan proper; and active steps were being taken to build up production still further. American submarines had sunk at least two cargoes of concentrate. In this instance Japan can nevertheless be said to have succeeded in deriving notable profit from an occupied country.

The activity of the American fleet in Philippine waters in the third quarter of 1944, the American invasion of the islands in October, and subsequent events in connection with the war probably cost Japan access to all of the copper of the Philippines before the end of the year.

Turkey.—The two chief copper areas in Turkey are at Erganimaden and Murgul. Until recently some blister copper was produced at Kuvashan near Murgul, but reserves at this property are reported to be near exhaustion. All three properties are subsidiaries of Eti Bank. Ergani is the principal producer. It is said to have a large indicated reserve of ore containing 6.5 to 10 percent copper. Eti Bank reported that the average grade of ore produced in 1944 was 7.99 percent. Mining is by open-pit methods, and the property is equipped with a smelter and small fire-refining plant. Blister output, in metric tons, is reported as follows: 1939, 4,236; 1940, 4,754; 1941, 8,100; 1942, 5,180; and 1943, 7,030. Refined copper is reported as follows: 1939, none; 1940, 2,076; 1941, 910; 1942, 2,205; and 2,200 in 1943. Plans call for larger production of blister copper in 1945, but a shortage of refractory brick may result in the closing of the plant. The predominant ore minerals at Murgul are pyrite, chalcopyrite, and bornite. The average tenor of ore is reported to be about 2½ percent copper. "Uncovered" reserves in 1943 were reported as 2,000,000 tons. New equipment to be installed at this mine after the war comprises a 1500-ton flotation mill and a smelter. The following amounts of blister copper were recovered from ore at the Kurvashan mine: 1939, 2,500 metric tons; 1940, 1,924; 1941, 1,417; 1942, 857 and 1943, 485. There are two small electrolytic installations in Turkey, one at the Turkish military factory at Karik Kale and the other, privately owned, at Yunus near Istanbul.

United Kingdom.—The turning point in the supply-requirements balance for the United Kingdom was reached in 1944, and at the end of the year the British Government was planning cancellation of contracts with Empire producers and release of copper to the United States under reverse Lend-Lease arrangements. Announcement was

essentially that contracts with producers would not be renewed after January 31, 1945. Market reports in December stated that for all applications for metal for civilian consumption were reviewed sympathetically, the principal difficulty being that permission for use of metal was contingent on the provision that the use should not take labor from priority work. In a statement in the Metal Market (London) of July 14, 1944, consumption of new copper from the beginning of World War II to the end of 1942 was estimated to be more than doubled. Consumption, according to the article, rose from 300,000 or possibly 600,000 tons a year, compared with an annual average of about 251,000 tons in 1934-38. The United Kingdom is one of the largest copper-importing countries; according to the Metal Market (London) of January 5, 1945, imports reached 492,000 tons in 1943, compared with a prewar average of 262,000 tons. These imports cover what is termed "retained imports." An article in the December 16, 1944, issue of the American Metal Market indicates that it happened to British exports of copper and brass materials as a result of the war, as follows:

Copper and brass exported from Great Britain, 1938 and 1943, in long tons (reexports and shipments for use of United Kingdom forces abroad excluded)

	1938	1943
Sheet (including rough)	10,468	111
Bars, sheets, strips, etc.	4,365	1,577
Wires and rods	11,349	2,137
Castings	1,298	693

Alloys of copper (other than nickel):		
Bars, sheets, etc.	3,218	370
Wires, rods, strips, etc.	7,489	461
Castings, etc.	1,845	1,046
Manufactures	1,702	1,092
Brass	1,223	712
Manufactures	6,095	2,370

Yugoslavia.—The famous Bor mine, located near Zajecar in the district of Moravska, about 90 miles southeast of Belgrade, was taken back from the Germans by the Yugoslav Partisan forces in the last quarter of 1944, thus denying to Germany what had been its chief source of newly mined copper since June 1940. Owing to conditions prevailing in Yugoslavia during much of the war period, there is considerable doubt that the Germans were able to maintain production at near capacity levels despite their desperate need for this metal. Mine production, so far as data are available, was 64,200 metric tons in 1939. According to the Mining Journal (London) of March 1945, the speedy advance of the Yugoslav and Russian armies prevented planned demolition at the property, but 3 months were required, nevertheless, to make necessary repairs to mine, foundry, and blast furnaces.

GENERAL SUMMARY

The outstanding feature of the lead industry in 1944 was the decrease in new supplies, which failed to balance a high level of consumption. Production from domestic mines, which is the principal source of new supply, continued to decline, largely owing to a severe shortage of manpower. Imports of refined lead—a ready source of immediately usable metal—were lower, consumption was maintained at a high level, and Government stocks of refined lead were steadily reduced to a point considered below the margin of safety. At the end of the year a sweeping revision of existing General Preference Order M-38 was announced by the War Production Board to restrict consumption further and thereby help to ease a situation that had grown critical. The end of the European phase of the war in May 1945 was accompanied by signs of gradually diminishing military requirements, but the backlog of civilian needs for lead during the period of partial reconversion will maintain demand at a high level. The prospect for 1945 is one of the continuing insufficient supply for all potential consumers but of adequate supply for military and essential civilian requirements.

Refined primary lead production from domestic and foreign ores and foreign base bullion decreased 1 percent in 1944, the total being only 4,849 short tons less than the 1943 output. Year-end stocks at domestic refineries (physical inventory) were less than half the total at the beginning, and consumers' inventories were 22 percent lower.

Total imports of lead in all forms during 1944 showed a gain of less than 1 percent. An increase in receipts of lead in ore, concentrates, and matte—largely from Newfoundland and Australia—offset a decline in imports of refined lead, the principal source of which was Mexico. A substantial amount of reclaimed lead and lead scrap from Australia partly balanced the absence of base bullion from that country.

The established price of 6.50 cents a pound for lead at New York remained unchanged throughout 1944.

¹ This report deals primarily with the smelting, refining, and consuming phases of the industry. For full details of mining operations, see separate reports issued for the various States.

Noted figure.

¹ Data include lead imported for immediate consumption plus material entering the country under bond. Includes 25,324 tons of foreign refined lead reexported, according to American Bureau of Metal Statistics; figures not available.

² Includes 3,574 tons of foreign lead reexported in 1942 and 11,258 tons in 1943, according to records of U. S. Department of Commerce.

³ Data not available.

⁴ Official maximum price fixed by British Ministry of Supply at £25 per long ton.

Figure 1 shows trends in the domestic lead industry since 1900.

Figure 1.—Trends in the lead industry in the United States, 1900-1944. Imports include lead in ore, base bullion, pig lead, and scrap; exports include pigs, bars, and scrap lead exported in manufactures with benefit of draw-back. Data on lead exported in manufactures with benefit of draw-back not available for 1944.

WAR AGENCY REGULATIONS

Lead remained under Government control throughout 1944, under War Production Board General Preference Order M-38, which provides for the regulation of shipments, deliveries, and a reserve pool for allocation. In actual practice the control of lead was confined to the allocation of Government-owned stocks of foreign lead and to prohibition of the use of lead for certain purposes; all essential uses were freed from control, subject, of course, to limitations imposed by virtue of regulations on the use of other materials needed for the manufacture of lead-containing products. As a result of a decrease in new supplies and Government stocks of refined lead were steadily reduced. To help ease the resultant critical supply position the War Production Board amended Order M-38, effective December 26, to restrict most civilian uses of lead to an annual rate of 60 percent of the 1944 level of consumption. Under the revised order, restrictions and availability of lead were defined under three listings: A, prohibited uses; B, end uses for storage batteries, cable covering, tetraethyl, and ammunition for military use only (for which lead was made available 100 percent) and for solders, bearing metals, brass and bronze for which the use of lead was unrestricted; and C, the greater portion of civilian uses with the restriction mentioned above. Greater restrictions were placed on other than essential uses by an amendment to the order on January 15, 1945, followed by the prohibition of certain end uses in the order by another amendment on February 1. Because the lead supply became increasingly critical, permissible uses of the metal were again curtailed, in an amendment to the order on March 31, to include only end products. A list of 64 permissible uses was substituted for the previous lists A, B, and C which covered restricted uses, unrestricted uses, and quota percentage restrictions.

To conserve further the foreign supply of lead available to the United States for war purposes, War Production Board General Imports Order M-63—governing imports of strategic materials—was amended, effective February 14, to place collapsible lead tubes, storage batteries, and lead foil under import control. Later, in April, another amendment included lead disks, slugs, and other semifabricated forms manufactured in whole or in part from lead or lead alloy.

Limitation Order L-180, affecting storage batteries, was amended in April 1945, to insure that the lead shortage was not reflected in the quality of replacement storage batteries produced in 1945 and to prevent the sale of batteries except under conditions in which replacement was imperative.

The Premium Price Plan for overceiling payment for production of lead in excess of quotas was maintained throughout 1944. A brief outline of the Premium Price Plan and an accompanying table giving production and payments from 1942 through 1944 are given in this chapter under the heading Prices.

RECIPROCAL TRADE AGREEMENTS

Marked opposition was voiced early in 1945 against certain proposals embodied in a bill (H. R. 2652) placed before Congress to extend the Reciprocal Trade Agreements Act. The lead industry as a whole opposed the proposed delegation of power to the President to make a further cut of 50 percent in the rates of duty prevailing

January 1, 1945, and asked that any extension of the act be limited to the war. The cause for alarm was certain language in the measure that could be interpreted to make permanent the temporary 50-percent reduction under the existing Mexican Trade Agreement of 1942. As finally written and passed by the Senate on June 19, the measure extends the act for 3 years and allows for as much as 50-percent reduction in the rates of duty prevailing on January 1. Any temporary reduction under wartime agreements remain temporary, however, and any cut in the duty will be with respect to the rates established by the 1930 tariff act. Under the "most-favored-nation" principle, any reduction embodied in a reciprocal agreement would apply equally to virtually all countries.

POSTWAR OUTLOOK

The outlook for lead for the few years following the war depends on the interrelated factors of production, imports and tariffs, consumption, and price. These in turn depend to a great extent on the outcome of the war in the Pacific and how soon the vast domestic productive capacity—as a whole—can be directed to peacetime pursuits under competitive conditions.

Production.—Mine production during the war period failed to reach the peacetime 1925–29 average of 664,230 tons owing to depletion of ore reserves in certain districts and to a general scarcity of manpower. A considerable proportion of the output since 1939 was reduced at the expense of the prospecting and development necessary to the sustained economic operation of a mine. The postwar availability of labor will not make up for depleted reserves, and some time will elapse before development can be again placed in a normal position in relation to actual mining. Conceivably domestic mines could fill the demand for new lead for a limited time, given adequate price and tariff protection, but the past partial dependence on foreign lead is expected to continue to an increasing extent as our resources are drained further.

Imports.—Postwar readjustments of international trade will be accompanied by an inevitable competitive world market for refined lead. The smelting countries—particularly those that depend largely on imported ore, such as France, Belgium, and the United Kingdom—will be actively seeking for such raw material in the very countries that were the source for much of our supply during the war period. In all probability such supplies as we may need will have to come from the Western Hemisphere—principally Mexico—in ore and as refined lead, as indications point to the production of other countries being absorbed by expanded industry at home and by shipment elsewhere than the United States. Any future lowering of tariff barriers, of course, will have its effect upon the flow of materials into the United States and upon domestic production.

Consumption.—The pent-up consumer demand to be filled in the immediate postwar period will result in an annual consumption of new lead as metal and in ore of at least 500,000 tons—probably more—for some years. Aside from the large potential consumption of lead in batteries and tetraethyl for the forthcoming resumption of the manufacture of automobiles and their operation, the quantity of lead needed

for postwar construction at home and reconstruction abroad will far toward balancing the decreased use for direct military purposes.

Price.—Bonuses and premiums probably will be dropped eventually and prices freed of all control and allowed to return to a condition of normal fluctuations in a competitive market. In the absence of control, the price for lead immediately after the war may rise above the established wartime ceiling, but it is probable—taking the longer term view—that the price will be lower than at present, although not as low as the general prewar level. Assuming that some tariff protection will remain in force, the factors of demand by consumers and higher production cost to smelters and refiners will tend to keep the price on a plane relative to an expected generally higher-cost level for all commodities. The marked reduction in stocks during 1944 has largely precluded any possibility of postwar dumping of excess inventories of lead on the market with a resultant depressing effect upon the price. Further protection against such a possibility is given by the Surplus Property Act of 1944, which provides for stock-piling excess materials owned by the Government.

DOMESTIC PRODUCTION

Pig lead is produced at primary plants that treat ore, base bullion and small quantities of scrap and at secondary plants that process scrap exclusively. Both types of plants may make refined lead or antimonial lead. Because of the large quantity of hard lead—such as battery scrap—melted at secondary smelters, the output from this type of operation is essentially antimonial lead alloys. Figures for the production of refined lead and alloys at secondary plants are given in the section on Secondary Lead. The 17 smelters and refiners in the United States canvassed in 1944 (including one smaller smelter which reported for the first time) consumed 477,765 short tons (lead content) of ore, only 15 percent of which originated in foreign countries.

REFINED LEAD

Despite the continuing labor shortage, the 10 primary refineries in the United States were able to produce 476,131 tons of refined lead, 1 percent above the 1943 output of 471,475 tons.

Of the 464,763 tons of primary lead produced in 1944, domestic ores and base bullion supplied 85 percent, and 15 percent was derived from foreign ores and imported base bullion. In 1943 the origin was 87 percent domestic and 13 percent foreign. Again, as in 1943, the quantity of refined lead produced from foreign base bullion was negligible. Imports of this material, from Mexico and Peru, amounted to only a few tons. This suggests that practically the entire Mexican production of base bullion (a large proportion of which was exported to the United States each year before 1942) continues to be refined in Mexico. The following table gives the production of refined lead by country of origin of the ore. Details of the sources of lead from domestic ores are given in the section on Mine Production.

ANTIMONIAL LEAD

Antimonial lead production at primary refineries decreased 8 percent to 57,902 tons in 1944. The distribution of the lead is shown in the following table, according to source. The marked increase in the lead content recovered from scrap in 1943 and 1944 is due largely to the greater quantity of battery lead plates being smelted for the specific production of antimonial lead. The antimony content showed an increase for the first time since 1940. The probable reason for this increase to 8.1 percent antimony in 1944 from 5.3 percent in 1943 is the decrease in small-arms ammunition production in 1944 and consequent smaller demand for the lower percentage antimonial lead used for bullet core rod. In addition to antimonial lead produced as a byproduct of the process of refining base bullion, a much larger quantity was obtained from smelting antimonial lead scrap at secondary smelters. Production data from lead-smelting plants handling scrap materials exclusively are summarized in the following section and discussed in detail in the chapter on Secondary Metals—Non-ferrous.

Antimonial lead produced at primary lead refineries in the United States, 1940-44

¹ Revised figures.**SECONDARY LEAD**

Although some scrap lead is treated at primary smelters and refineries, the greater part is received at a large number of plants that treat secondary materials exclusively. Secondary lead is recovered in the form of refined lead, antimonial lead, and other alloys. Recovery at primary and other plants in 1943 and 1944 is shown in the following table. Secondary lead recovered in 1944 was 3 percent less than in 1943 and was equivalent to 71 percent of the total refined primary lead produced in the United States. Further details appear in the chapter on Secondary Metals—Nonferrous.

¹ Revised figures.**LEAD PIGMENTS**

The principal lead pigments are litharge, white lead, red lead, sublimed lead, leaded zinc oxide, and orange mineral. These products are manufactured for the most part from lead ore and metal. Details of the production of lead pigments and salts are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

MINE PRODUCTION

The mine production of recoverable lead (including that made into lead pigments) in the United States and Alaska decreased 8 percent in 1944 and was 16 percent under the war-period peak reached in 1942. Of the 23 States and Alaska where lead is commonly produced, 14 States and Alaska showed a decline in output, 7 States recorded a

and remained the same, and 1 showed no production for the second consecutive year. The reason for the decline in production was nearly a critical shortage of manpower.

Production of recoverable lead in the United States, 1925-29 (average) and 1940-44, by States, in short tons

Lead mining is centered largely in three areas—Southeastern Missouri; the Tri-State area (Joplin region), embracing Southwestern Missouri, Southeastern Kansas, and Northwestern Oklahoma; and the Western States (principally Idaho, Utah, Colorado, Arizona, and Montana). Of the total produced in the United States, the greater part is supplied from a relatively small number of large mines. The Southeastern Missouri district continued to be the largest lead-producing area, supplying 41 percent of the total domestic output despite a 5-percent decline from 1943. The greater part of the production from this district, as in the past, came from four mines of the J. Joseph Lead Co. The Tri-State area—principal zinc-producing district in the United States—supplied 7 percent of the total United States lead output compared with 8 percent in 1943. The largest producer in the region was the Eagle-Picher Mining & Smelting Co. The Western States contributed 50 percent of the total domestic production in 1944, Idaho being the largest producer of the group and second-largest in the United States, notwithstanding a production decline of 13 percent. Ten properties in Idaho produced three-quarters of the State total lead output, and of the total the greater part was from zinc-lead ore and old tailings, the remainder being

principally from lead ore. Utah again ranked second among the Western States and third in the United States, although the output of 52,519 tons of recoverable lead was 20 percent less than in 1943 and the lowest production since 1921. The United States & Louisiana property in the Bingham district, operated by the United States Smelting, Refining & Mining Co., was by far the largest lead producer in the State. In Arizona, four mines furnished two-thirds of the State total lead output which advanced 22 percent above that of 1943. One-half of the production from Colorado and Montana came from three mines in each of these States. Additional details on production by mines and districts can be found in the State chapters.

Mine production of recoverable lead in the United States, by districts that produced 1,000 tons or more during any year, 1940-44, in short tons

American
Stocks
refin-
duce soft

and plus foreign lead smelted and refined in the United States and used for domestic consumption. According to the monthly reports released by the American Bureau of Metal Statistics, combined stocks of refined lead and antimonial lead fluctuated during the first months of 1944, but for the remainder of the year the trend was upward. From 27,996 tons on hand at the end of November 1943, stocks advanced to a year-end total of 33,090 tons and continued to increase to 37,590 tons on January 31. This was followed by a drop to 34,379 tons by the end of March, with a subsequent sharp rise to 39,430 tons on May 1, the highest point reached in 1944. Throughout the remainder of 1944 stocks steadily declined—with the exception of a minor increase at the end of November—the year-end total was 29,536 tons, a net decrease of 41 percent from the beginning of 1944.

Stocks at end of year at smelters and refineries in the United States, 1940-44, in short tons

	1940	1941	1942	1943	1944

The results of the Bureau of Mines annual survey of primary lead smelters and refineries showed stocks of 36,464 tons of refined lead at plants on January 1, 1944, and 16,788 tons on December 31, 1944. In these same plants antimonial lead stocks decreased from 3,682 short tons (lead content) at the beginning to 3,387 tons at the end of 1944. In terms of lead content, stocks of ore at 17 operating smelters and refineries (including 1 small plant not canvassed in 1943) increased 16 percent from 50,935 tons to 60,480 during the same period. The inventory of base bullion at refineries that receive base bullion as a raw material and at smelters that produce base bullion for shipment to refineries totaled 8,110 tons at the beginning of January and 6,606 tons at the end of December 1944. Stocks of "in process" base bullion or work lead at 5 combination smelter-refinery plants are not included in reports to the Bureau of Mines. No direct comparison can be made between these data and the figures of the American Bureau of Metal Statistics. Figures reported to the Bureau of Mines represent physical inventory at the plants, irrespective of ownership, and do not include material in process or in transit.

Consumers' stocks.—According to reports from 570 consumers' plants 89,743 tons of domestic and foreign refined lead were in stock on December 31, 1944, a 22-percent decline from the 115,152-ton inventory on hand at the end of 1943.

Consumers' stocks of refined soft lead at the end of 1943 and 1944, by grades, short tons

Dec. 31, 1944	28,789	13,690	44,425	2,839	89,743	10.5

¹ Revised figures.

Government stocks.—In addition to industry-owned stocks, a sizable though diminishing supply of Government-owned lead was held at various depots throughout the United States for release through allocation to consumers as needed. According to reports submitted to the Tin-Lead-Zinc Division of the War Production Board, Government stocks totaled 90,454 tons of refined lead on December 31, 1944, compared with 173,875 tons of refined lead on January 1, 1944.

DOMESTIC CONSUMPTION

A survey of 570 plants in 1944 (530 (corrected figure) in 1943) representing an estimated 90 percent of the consumers of refined lead showed a total consumption of 722,820 short tons of refined lead, a gain of 7 percent over 1943. Some secondary as well as primary refined lead is included in this figure. Antimonial lead, unrefined scrap lead, and lead in alloys are excluded. The additional number of plants covered in the 1944 survey include for the most part small consumers that did not report in previous years. The lead consumed by these plants was small in relation to the total and does not measurably affect the trends indicated by comparison with the 1943 data.

Of the total consumed, 22 percent was used to make red lead and litharge, 15 percent for cable covering, 11 percent for tetraethyl, 10 percent for storage batteries, 4 percent for sheet lead, 4 percent for ammunition, and the remaining 34 percent for a variety of products and uses shown in the accompanying table.

Consumption of refined lead in the United States, 1941-44, by uses, in short tons

	1941	1942	1943	1944
Ammunition	32,959	48,025	64,023	31,479

Weights and ballast	(1)	(1)	9,260	22,964
Other	64,506	33,746	64,940	33,646
Total	812,647	607,111	675,465	722,820

¹ Included under "Other."

Distribution of the total consumed by related uses shows 51 percent consumed for metallic products, 31 percent for pigments, 13 percent in chemicals, and 5 percent in miscellaneous uses such as painting, galvanizing, lead plating, and weights and ballast.

Reports to the Tin-Lead-Zinc Division of the War Production Board indicate that the consumption of primary, antimonial, and secondary lead totaled 1,119,000 tons in 1944 compared with 1,113,000 tons in 1943.

The following table shows the calculated apparent shipments of refined primary lead to domestic consumers. The apparent shipments of 775,095 tons in 1944 are probably more nearly correct than the actual receipts of 697,411 tons reported by consumers, because of complete coverage of the survey.

PRICES

The two major markets for lead in the United States are New York and St. Louis; much of the lead produced in this country is sold at prices normally based upon quotations in these markets. Since suspension of the London Metal Exchange dealings in September 1939 the London market has had no direct influence on New York quotations, and the differential between St. Louis and New York prices has remained at 0.15 cent a pound, an amount approximating the freight charges between the two points.

The ceiling price for common lead—6.35 cents a pound, St. Louis, and 6.50 cents, New York—remained unchanged throughout 1944. For comparison it is of interest to note that the average price received by the primary producers for all grades of refined lead (excluding antimonial lead) sold in 1944 was 6.4 cents a pound, f. o. b. plant, the same as in 1943. The 1944 price of 8.0 cents for lead, which appears in the separate State chapters, represents the above weighted average price received for refined lead plus the increment—in terms of cents per pound based upon the total domestic mine output of recoverable lead—of \$13,745,815 in overquota premiums and special mine contracts paid by the Metals Reserve Company.

The Premium Price Plan, whereby producers (miners) of lead (copper and zinc were also included in the plan) receive increments above the ceiling price (through Metals Reserve Company) for over quota production, was maintained throughout 1944. As the plan operative only until July 31, 1945, Congress passed the Hayden-McFarland bill, S. 502, on June 14, 1945, to extend the time limit to June 30, 1946. More complete details of the scope of the Premium Price Plan—which was effective February 1, 1942—can be found in the chapter on Lead in Minerals Yearbooks for 1942 and 1943. In May 1945 the Office of Price Administration released a comprehensive compilation of data showing production of copper, lead, and zinc under the Premium Price Plan since February 1942, at the various quota levels and the payments made. The salient statistics from this report with reference to lead, are given in the following table.

¹ Premium Price Plan effective Feb. 1, 1942; data refer to February-December, inclusive.

² Production of Tri-State lead from Metals Reserve Company agency, Joplin, Mo., all other from Bureau of Mines monthly reports. These data are preliminary and do not exactly equal final annual totals for the United States.

³ Data on premium payments and Metals Reserve Company mine contract payments from Metals Reserve Company. All payments shown are subject to correction due to additional payments as a result of retroactive quota adjustments, late reports by smelters and custom mills, etc.

⁴ All average prices shown include Office of Price Administration ceiling price of 6.50 cents a pound for lead.

The official London maximum price of £25 per long ton, duty paid, Empire and foreign lead, remained unchanged during 1944.

FOREIGN TRADE²

Imports.—During 1944 imports of lead continued at a high rate—nearly the same as in 1943—but considerably below the record total of 1942. The greater part of the total pig lead imported came from Mexico, as usual, but a substantial tonnage was from Peru. The marked drop in the quantity from Mexico reflects the lower production of that country due to the strike against mining and smelting companies from June 8 to August 11 and to the extremely poor condition of the railroads and rolling stock, which hampered transportation of lead from the mines to the smelters. Receipts of lead in ore and matte, which constituted 30 percent of the total in all forms, were 35 percent higher than in 1943 owing largely to a marked increase in imports from Australia, Newfoundland, and Peru which more than offset a substantial decline from Africa and Bolivia. Imports of lead in base metal dropped to only a few tons, owing to a complete absence of receipts of this material from Australia. Four countries furnished 93 percent of the total lead in all forms imported into the United States in 1944: Mexico 53 percent, Peru 20, Newfoundland 10, and Australia 10, compared with 68, 7, 4, and 10 percent, respectively, for a total of 89 percent in 1943.

¹ Includes 25,324 tons of foreign lead were reexported, according to American Bureau of Metal Statistics; figures not available.

² Includes 3,574 tons of foreign lead were reexported in 1942, 11,258 tons in 1943, and less than 1 ton in 1944.

³ United Kingdom of Great Britain and Northern Ireland.

WORLD ASPECTS OF THE LEAD INDUSTRY

The rapid succession of events in 1944 and early 1945, culminating in the unconditional surrender of Germany in May 1945, opened door to revealing greater detail regarding the lead industry in foreign countries than had been available since 1939. Censorship restrictions—imposed for reasons of security—have been removed by the governments of most of the lead-producing countries, and unrestricted information regarding European countries formerly under Axis control is beginning to flow by way of official channels. Nevertheless, it is not yet possible to present a complete picture of world production and consumption of lead during the years of the European phase of the war. The lead position of the United Nations was satisfactory in 1944, and, although consumption probably did grow somewhat, this increase was accomplished at the expense of accumulated stocks owing to an indicated over-all decline in production.

World production of lead, 1933-44, in metric tons¹

¹ By countries where smelted, but not necessarily refined.² Data not yet available; estimate included in total in 1939.³ Approximate production.⁴ Unoccupied China.⁵ Exclusive of secondary material (Metallgesellschaft, Frankfurt on the Main).⁶ Includes small tonnage of lead contained in exported ore and concentrates. Separate figures not available.⁷ Figures cover lead refined from domestic and foreign ores; refined lead produced from foreign base bullion not included.

REVIEW BY COUNTRIES

Argentina.—The Aguilar mine of the Compañía Minera Aguilar, S. A., subsidiary of the St. Joseph Lead Co., continued to be the leading producer in 1944. Lead concentrates totaling 37,887 metric tons, containing 75 percent lead, were produced in Argentina in 1944, of which approximately 35,000 tons were from Aguilar.

India.—A shortage of manpower continued to plague the mining industry during 1944. A reduction of about 50,000 long tons in the amount of ore treated by the Zinc Corp., Ltd.—due to shortage of labor—was counter-balanced to some extent by an improvement in the grade. Although normal exploration and development have been continued to meet production requirements, the ore reserves have declined to roughly 4,000,000 tons, averaging 11.5 percent zinc and 11 percent lead. The problem of supplying enough water has become much concern. The lead content of concentrate produced in 1944 was reported to total 75,834 short tons as against 79,016 tons in 1943.

Isa Mines, Ltd., is reported to have 8,000,000 long tons of zinc ore in reserve averaging 8.6 percent lead and 8 percent zinc. This total excludes a much larger tonnage of material containing as little as 4 percent lead, which is not considered ore under existing conditions.

Production data are being released by the Australian authorities, but official figures had not been received at the time of writing (June 1944). Data from an unofficial source indicate that total mine production of lead in Australia was 197,300 short tons in 1944 (211,600 short tons in 1943).

Bolivia.—Mine production of lead in Bolivia decreased from 11,387 metric tons (lead content) in 1943 to 9,047 tons in 1944. All ores and concentrates are exported, some going to Argentina for smelting and some to the United States. Again, as in 1943, exports declined because of an increase in prices of materials, cost of labor, and the difficulty of transporting ores from the country. The Matilde mine at Lake Titicaca, owned by Compañía Hochschild, was reported to have as of 1944—some 4,000,000 metric tons of ore in reserve containing an average of 18.7 percent zinc and 2.5 percent lead, 0.7 percent copper, and 1.75 ounces of silver per ton.

Brazil.—A new lead smelter was built in 1944 by Plumbum, S. A., at Pampas, State of Paraná. The plant is reported to include a No. 4 sintering hearth, a No. 4 Mace blast furnace, and a Parkes converter refinery with a capacity of 20 metric tons of refined lead daily. This smelter is the second to be constructed in Brazil, the first being the Apiai smelter at Apiai built and operated by the São Paulo Government. The Apiai plant, which had a daily capacity of 10 tons of refined lead, shut down in October 1942 and has not operated since, although a new refinery is reported under construction.

Burma.—The famous Bawdwin lead-zinc mine and smelter—which before the war produced 80,000 tons of lead a year—was reported captured from the Japanese early in 1945. Not long before recovery of the mine the property was bombed by the Allies. As the ore reserves last reported before the war indicated a relatively short life owing to this centuries-old mine, doubts have been expressed as to the mine opening if damage is found to be severe.

Canada.—Mine production of lead in Canada decreased from 229,930 short tons (revised) in 1943 to 151,611 tons (preliminary) in 1944. The output of refined lead in 1944 was 143,757 tons (preliminary) compared with 224,493 tons in 1943. Over 90 percent of Canada's production of lead was from the Sullivan mine of the Consolidated Mining & Smelting Co., which operates the only Canadian lead smelter and electrolytic lead refinery. The plant is at Trail, British Columbia.

In 1943 a 250-ton mill was reportedly to be built at the Sherbrooke, Quebec, property of the Aldermac Mining Corp. Production was begun at the completed mill in July 1944, on ore averaging 7 percent zinc, 2.5 percent copper, 2 percent lead, and containing some gold and silver.

In July 1944 the Department of Munitions and Supply announced suspension of operations at four high-cost lead-zinc properties which had been producing for the Metals Reserve Company, an agency of the United States Government. The labor and materials formerly utilized at these properties, the Twin "J" mines, Duncan, British Columbia, Kootenay-Florence mine, Ainsworth, British Columbia, Lake Geneva mine at Benny Siding, Ontario, and Tetreault mine, Notre Dame des Anges, Quebec, have been released for more urgent needs.

France.—The lead-smelting industry in France depends largely on imported ores, but in recent years new mines have been developed and the output of lead concentrates has shown an increase. Production of lead (content of lead in ores and concentrates) from 1938 through 1944, in metric tons, was as follows:

Year	1938	1939	1940	1941	1942	1943	1944
Production.....	4, 220	5, 410	2, 440	3, 870	5, 770	5, 471	3, 5

In 1943 Germany ordered France to increase mine production up to 1,000 tons a month, but the policy of the French was to reduce output when possible and divert labor for development, thereby producing less lead for export to Germany. The lead smelter at Ceilhes was taken over by Société Minière at Métallurgique de Penarroya and reopened at the end of 1944, but operation of the plant will depend upon the obtaining of imported lead concentrates and the availability of coke.

French Morocco.—Production of lead from 1940 through 1944 was as follows, in metric tons:

Year	1940	1941	1942	1943	1944
Ore and concentrates.....	30, 739	13, 918	9, 000	9, 570	13, 468
Lead content.....	22, 132	10, 020	6, 500	6, 890	9, 233

Mexico.—Production of lead in Mexico declined from 218,126 metric tons (lead content in ore) in 1943 to 185,282 tons in 1944 due to circumstances unfavorable to mining. A general labor strike against some 140 mining and smelting companies was called on June 8 and was not completely settled until August 11. The Labor Ministry announced that, with the strike settled, a general increase in mineral production at most of the properties was expected. However, severe floods in the fall of 1944 interfered with mining operations and the shipment of ore to smelters. The shortage of railway cars and generally run-down condition of the railway system further complicated an already critical situation.

Newfoundland.—The mine production, in terms of lead content of all concentrates produced, amounted to 29,661 short tons in 1944

and with 32,940 tons in 1943. The bulk of the exports of concentrates continued to go to the United States.

Peru.—The lead content of concentrates produced in Peru during 1944 is estimated to be 52,501 metric tons compared with 47,810 tons in 1943. This estimate is based upon reports of the major lead-producing companies. Exports of lead from Peru—which went to the United States—amounted to 56,747 tons of refined lead and 1,195 tons of lead contained in ore, concentrate, and other products. Comparable totals for 1943 were 20,691 tons and 5,324 tons, respectively.

The greatest part of the lead produced in Peru is derived from the gold-silver-lead-zinc ores mined by the Cerro de Pasco Corp., Department of Junin. Cia Minera Atacocha, S. A., an important producer of lead, reported the production of 58,200 tons of ore in 1944, averaging 13.5 percent lead and 14.0 percent zinc.

The Over-All Metals Agreement between the Peruvian Government and the United States Commercial Company was renewed on July 8, 1944, effective as of July 1, 1944, when the previous agreement expired. The latest agreement provides for the continued purchase by the United States Commercial Company of lead in ores and concentrates and electrolytic lead at the same price as previously furnished. The Peruvian Government was advised on December 1, 1944, that 3 months after this date lead ores and concentrates will be purchased at the rate of 10,000 metric tons a year.

The Oroyo lead smelter—which constitutes an important factor in the progress of the mining industry in the Republic—recovered 46,000 metric tons of lead in 1944 (43,171 tons in 1943). About 70 percent of the lead produced at Oroyo is derived from mines other than the Cerro de Pasco.

Spain.—Production of lead concentrates in Spain during 1944 amounted to 43,000 metric tons (47,913 tons in 1943). Refined-lead output was 32,000 metric tons compared with 34,080 tons in 1943. The drop in output was due in part to interruption of traffic with Germany. Owing to the great decline in lead production in recent years, smelter capacity is about five times current output. Unless changes are made in the internal economy of the country, Spain will continue to supply its own needs for lead, but exports will remain important.

Sweden.—The completion of a new lead smelter at Landskrona in 1944 brings to four the number of plants producing lead in Sweden, with a total capacity amounting to about two-thirds of the total prewar consumption of approximately 35,000 metric tons. The new plant uses ore obtained from mines in Central Sweden and a new mine in the northern Province of Vaesterbotten. The lead concentrates were formerly shipped to Germany. It is of interest to note that before the war lead was not smelted in Sweden.

U. S. S. R.—Official data from Russia have not been available for the past several years, but recent reports indicate that 125,700 metric tons of lead were produced in 1943.

GENERAL SUMMARY

The significant feature of zinc in 1944 was that the industry, despite a most serious obstacle in the form of a critical manpower shortage met all essential demands—civilian as well as military—by a comfortable margin. Production decreased as did imports, but the overall new supply was sufficient to balance a rising consumption under relaxed Government control, with enough excess to add markedly to an already high record level of stocks. The prospect for 1945 is one of continuing insufficient supply to meet all demands, but of adequate supply for military requirements and all civilian uses other than nonessential.

Domestic mine output was 3 percent less in 1944, and smelter production of primary slab zinc from both domestic and foreign ores was lower, the total being 8 percent below the record of 1943. Year-end stocks at domestic smelters were 38 percent more than at the beginning, but consumers' inventories decreased 28 percent.

Total imports of zinc in ore and concentrates and as slab zinc decreased 18 percent. The greater part, as usual, was in the form of concentrates, largely from Mexico and Canada.

The established ceiling price of 8.25 cents a pound at St. Louis for Prime Western zinc was unchanged during 1944, and the premium-price plan for overquota mine production was maintained throughout the year.

¹ This report deals primarily with the smelting branch of the industry. Full details of zinc mining are given in the various State reports. As some zinc ore is used directly in the manufacture of zinc pigments, see chapter on Lead and Zinc Pigments and Zinc Salts.

Figure 1 shows trends in the zinc industry since 1900.

WAR AGENCY REGULATIONS

During 1944 Government controls with regard to zinc were greatly relaxed. The use of zinc was liberalized by an amendment to War Production Board Conservation Order M-11-b on January 1, 1944, and on September 15 General Preference Order M-11, which relates to slab zinc, was amended to discontinue the system of allocation previously used to regulate shipments to consumers. On September 13, 1944, again on October 11, Order M-11-b was further modified, and with the exception of a list of 40 prohibited items, zinc could be shipped with no restrictions, subject, of course, to limitations imposed by existing regulations on the use of other materials needed for the manufacture of zinc-containing products. General Preference Order M-11-b, covering deliveries of zinc dust, as amended December 13, 1943, became effective January 1, 1944, and continued without change during 1944.

The premium-price plan, for overceiling payment for production of zinc in excess of quotas, was maintained throughout 1944. A brief outline of the premium-price plan and an accompanying table showing production and payments from 1942 through 1944 are given in this chapter under the heading Prices.

RECIPROCAL TRADE AGREEMENTS

Marked opposition was voiced early in 1945 against certain proposals embodied in a bill (H. R. 2652) placed before Congress to amend the Reciprocal Trade Agreements Act. The zinc industry as a whole opposed the proposed delegation of power to the President

FIGURE 1.—Trends in the zinc industry in the United States, 1900-1944. Imports for consumption of slab and sheet zinc are not shown. Before 1936 they seldom exceeded 500 tons annually, but in recent years they have increased, amounting to 10,164 tons in 1940, 40,559 tons in 1941, 36,402 tons in 1942, 56,155 tons in 1943, and 63,641 tons in 1944.

to make a further cut of 50 percent in the rate of duty prevailing on January 1, 1945, and asked that any extension of the act be limited to 1 year. The cause for alarm was certain language in the measure that could be interpreted to make permanent the temporary 50-percent reduction under the existing Canadian Agreement of 1938 and the Mexican Trade Agreement of 1942 and empower the Executive Branch of the Government to make tariff reductions as much as 75 percent below the rates established by the Tariff Act of 1930. Under the "most-favored-nation" policy, the original reduction embodied in the Canadian and Mexican agreements extended to virtually all countries and would apply equally to the present measure. On June 19 the Senate voted favorably on the bill despite all opposition.

SUPPLY OF ZINC CONCENTRATES

The greatest factor causing the 3-percent decrease in domestic mine production in 1944 was the shortage of labor. Under the circumstances of manpower difficulties, which were increasing by the end

of the year, the total of 718,642 tons of recoverable zinc produced was a creditable achievement. This output, coupled with a large tonnage of imported zinc concentrates, was sufficient to maintain production at smelter and pigment plants at high levels and thereby supply controlled consumption in 1944.

The requirements for zinc in 1945, as estimated by the War Production Board at the end of 1944, were greater than the potential supply from a decreasing domestic output and lower quantity of concentrates available for import. Indications point to a lower overall new supply of concentrates in 1945. Domestic mine production is expected to decrease in the face of continuing labor difficulties, higher costs, and lower-grade ore, and the foreign supply, principally from the Western Hemisphere, undoubtedly will be lower. Mexico and Canada, the chief sources of imports of zinc concentrates, also face the problem of manpower, and shipments from Mexico will continue to be hindered by the extremely poor condition of the transportation system in that country. However, it appears likely that earlier estimates of military zinc requirements (particularly for brass) will be modified—as a result of the German surrender in May—to the point where the lessened supply will be adequate for all demands except nonessential uses.

SMELTING CAPACITY

Despite a continued high level of requirements in 1944, slab zinc production of 918,339 tons was below the record level of 1943 and short of early estimates, owing to a serious labor shortage. Full capacity of smelters was not utilized, and as the effect of the labor shortage was felt at all plants the potential tonnage of zinc lost was appreciable. According to reports to the Bureau of Mines, the zinc-producing plants in the United States on December 31, 1944, had a stated annual capacity to produce 1,033,000 tons of slab zinc under normal operating conditions, allowing for necessary shut-downs for repairs. This figure, which is 5 percent under the reported capacity at the end of 1943, indicates that the 1944 output was 89 percent of capacity as compared with 91 percent in 1943. Primary smelters operated at 86 percent of a stated 670,000-ton capacity (90 percent of a 799,000-ton capacity in 1943), electrolytic plants at 94 percent of a 338,000-ton capacity (98 percent in 1943), and secondary smelters at 57 percent of a 43,000-ton capacity (54 percent of a 44,000-ton capacity in 1943).

The facilities for redistillation of the lower grades of zinc into high-grade metal were used throughout 1944 but to a much less extent than in 1943.

No additional smelting capacity was under construction at the end of 1944, and no units additional to existing plants were planned.

POSTWAR OUTLOOK

The outlook for zinc for a few years after the war depends upon the interrelated factors of production, imports and tariffs, consumption, and price. Because zinc is so closely woven in the over-all pattern of domestic economy, the promptness with which forecast trends become apparent depends upon how soon the vast domestic productive capacity, as a whole, can be directed to peacetime pursuits under competitive conditions.

Production.—The mine production rate during the war period exceeded the peacetime 1925–29 average of 724,720 tons, but the peak of 768,025 tons in 1942 was 1 percent below the record established in 1926, and output since 1942 has declined steadily. The reason for the inability to maintain an increased production under the stimulus of war was the depletion of ore reserves in certain districts—principally the Tri-State—and a growing scarcity of manpower. The postwar availability of labor will not make up for depleted reserves, and some time will elapse before development—neglected in favor of greater output—can again be placed in a normal position relative to directly productive mining. It is doubtful if the high production rate of 1941–44 can be long maintained, and under postwar conditions of probable lower price and tariffs the level of output will be less, possibly in the range of 400,000 to 600,000 tons a year.

Imports.—Postwar readjustments of international trade will be accompanied by an inevitable competitive world market for slab zinc and zinc concentrates. The smelting countries—particularly those that depend largely on imported ore, such as Belgium, France, the United Kingdom, and Holland—will be actively seeking for such raw material in the very countries that were the source of much of the supply for the United States during the war period. In all probability such supply, sufficient to make up a deficit in domestic output of as much as 200,000 tons of zinc, will have to come from the Western Hemisphere—principally Mexico—as indications point to the production of other countries being absorbed by expanded industry at home and by shipment elsewhere than to the United States. Any future lowering of tariff barriers, of course, will have its effect upon the flow of materials into the United States and upon domestic production. Although current Government policy seems to favor tariff reductions, opposition is strong; the probable result will be a compromise allowing some protection in the postwar years but perhaps substantially below that afforded by the Tariff Act of 1930.

Consumption.—Consumer demand during the immediate postwar period no doubt will result in a minimum annual consumption of zinc as metal and in ore for pigments and chemicals of 650,000 tons and perhaps a maximum of 850,000 tons. The change in the use pattern for zinc during wartime is temporary, the emphasis being on brass manufacture rather than galvanizing. Following the war, galvanizing will increase and at least partly offset a decline in brass requirements for military orders, and the use of zinc-base alloys for die casting and stamping dies will return to the prewar level, probably resuming a rising trend. Although rolled-zinc products, zinc oxide, and other uses together consume a much smaller proportion of the total zinc used than either the galvanizing or brass industry, the amount so used will no doubt be equal to and quite likely above prewar levels.

Price.—Bonuses and premiums probably will be eventually dropped, and prices freed of all control and allowed to return to a condition of normal fluctuations in a competitive market. In the absence of control, the price for zinc immediately after the war may rise above the established wartime ceiling, but it is probable—taking the longer-term view—that the price will be lower than at present, although not as low as the general prewar level. Assuming that some tariff protection will remain in force, the factors of demand by the consumer and

higher production costs to the producer will tend to keep the price on a plane relative to an expected generally higher-cost level for all commodities.

DOMESTIC PRODUCTION

PRODUCTION OF PRIMARY AND REDISTILLED SECONDARY SLAB ZINC

The production of 869,302 tons of primary slab zinc in 1944—although high in comparison with prewar figures—was 8 percent below the record established in 1943 and 3 percent under the total primary output in 1942. The use of foreign ore continued at a high level, but the slab zinc produced from this source was 15 percent below the comparable figure for 1943, the first reversal in the upward trend since 1936. Production from domestic ore was lower than in 1943 by 3 percent, thus continuing a trend that has been downward since 1941.

Production of redistilled slab zinc from zinc scrap gained 2 percent over the 1943 figure, the total output being derived almost equally from primary and secondary smelters. Figures for the output of remelted secondary slab zinc are not included with those for redistilled metal. In 1944 the production of slab zinc recovered by remelting purchased scrap amounted to 7,741 tons (7,406 tons in 1943). Zinc rolling mills and other consumers of slab zinc recover much more than this from their own plant scrap, but such metal normally does not enter the market as scrap and therefore is not measured statistically.

Primary and redistilled secondary slab zinc produced in the United States, 1940-44, in short tons

Year	Primary			Redistilled secondary	Total (excludes zinc recovered by remelting)
	Domestic	Foreign ¹	Total		
1940	589,988	85,287	675,275	48,917	724,192
1941	652,599	169,421	822,020	59,503	881,523
1942	629,957	261,915	891,872	53,195	945,067
1943	594,250	348,059	942,309	48,215	990,524
1944	574,453	294,849	869,302	49,037	918,339

¹ Most of the foreign ores smelted in the United States in 1940-41 originated in Mexico, Canada, Newfoundland, and Peru; in 1942, in Mexico, Canada, Argentina, Newfoundland, Australia, and Peru; in 1943, in Mexico, Canada, Argentina, Newfoundland, Australia, and Peru; and in 1944, in Mexico, Canada, Australia, Newfoundland, and Argentina.

² Represents a small tonnage of foreign slab zinc further refined into high-grade metal in the United States.

DISTILLED AND ELECTROLYTIC ZINC

Of the 1944 output of primary zinc, 63 percent was distilled and 37 percent was produced electrolytically compared with 65 and 35 percent, respectively, in 1943.

A decrease in demand for brass products for military uses—due to cut-backs in ammunition orders in the fall of 1944—was the principal factor that caused a 16-percent lower production of the higher grades of slab zinc. Although the available capacity for redistilling Selected and Prime Western zinc into high-grade zinc was only partly utilized, the electrolytic plants—that produce high-grade zinc—were operated at 94 percent of reported capacity. As a result, the output of primary electrolytic zinc was only 4 percent below the record total for 1943,

as compared with a 17-percent drop in production of distilled primary zinc.

Prime Western and Selected were the only grades of slab zinc that showed an increase in production in 1944, the total output being 23 and 19 percent, respectively, above the 1943 figures. In contrast Special High Grade decreased 14 percent and Regular (ordinary) High Grade 17 percent. The original first-stage smelter production of the two lower grades of zinc was somewhat higher than is indicated in the following table, but to avoid duplication the quantity of each grade consumed in the redistilling operation was omitted because the resultant Special and Regular High Grade slab zinc thus produced is included. It is believed that the data shown thus give a more accurate picture of the quantity and grades of zinc actually made available for use. Of the total 1944 production (comparable 1943 figures in parentheses), 31 percent (23 percent) was Prime Western, 27 percent (31 percent) Regular High Grade, 27 percent (30 percent) Special High Grade, 6 percent (6 percent) Intermediate, 6 percent (8 percent) Brass Special, and 3 percent (2 percent) Selected.

PRODUCTION OF PRIMARY SLAB ZINC BY STATES

Pennsylvania was the leading producer of primary slab zinc in 1944, thus regaining the position held every year but one since 1934. Montana, which displaced Pennsylvania for first place in 1943, was a close second in 1944 and was followed by Illinois. Of the States for which production figures may be released, Oklahoma, Idaho, and Arkansas occupied the next three positions, in order of decreasing importance. Pennsylvania and Oklahoma had greater production

ZINC DUST

All previous records for production of zinc dust were broken in 1944, the total output (26,511 tons) being 2 percent above the former high point reached in 1943 and 16 percent over the 1942 production. Zinc dust that is statistically reported is restricted to commercial grades that comply with severe specifications as to percentage of unoxidized metal, evenness of grading, and fineness of the particles. Zinc powder and blue powder are not included in the data. The zinc content of the dust produced in 1944 ranged from 95.0 to 99.6 percent and averaged 97.7 percent. Shipments of zinc dust totaled 26,576 tons, of which only 310 tons or 1 percent went to foreign countries (according to data submitted to the Bureau of Mines). This figure is possibly somewhat low, as Government purchases (of which a part was eventually shipped abroad) were not given separately, and a portion of this quantity no doubt was reported as domestic shipments. By far the largest group use of zinc dust is in chemical manufacturing, with sodium hydrosulfite the principal single item. According to data compiled by the Tin-Lead-Zinc Division of the War Production Board, 24,948 tons of zinc dust were used in 1944, of which 11,646 tons (47 percent) went into the making of sodium hydrosulfite. Production and shipments of zinc dust in 1944 were nearly in balance, and, as the amount consumed at manufacturers' plants was small, producers' stocks showed a moderate decrease from 1,521 tons (corrected figure) at the beginning to 1,287 tons at the close of the year.

The average price of zinc dust shipped to domestic consumers in 1944 was 10.1 cents a pound, the same as in 1943. The raw materials used to manufacture zinc dust are reviewed in the chapter on Secondary Metals—Nonferrous. The greater proportion of the production is from zinc scrap, principally galvanizers' dross. The remainder is made from zinc ore, slab zinc, and as a byproduct of zinc refining.

ZINC PIGMENTS AND SALTS

The principal zinc pigments are zinc oxide and lithopone, and the principal salts are the chloride and sulfate. These products are manufactured from various zinc-bearing materials, including ore, metal, scrap, and residues. Details of the production of zinc pigments and salts are given in the chapter on Lead and Zinc Pigments and Zinc Salts.

MINE PRODUCTION

Mine production of recoverable zinc (including that made into zinc pigments) in the United States decreased 3 percent in 1944. A decline in output from 11 of the 21 zinc-producing States could not be balanced by gains from the other States. The continued drop in production from the high point reached in 1942 was essentially due to the manpower shortage, which reached a critical stage in 1944.

Zinc-mining operations are centered in five localities—the Tri-State area of Southeastern Kansas, Southwestern Missouri, and Northeastern Oklahoma; Tennessee-Virginia; Essex County, N. J.; St. Lawrence County, N. Y.; and the Western States (principally Idaho, New Mexico, Colorado, Utah, Montana, and Arizona in descending order of productivity in 1944). The Western States output advanced 5,110 tons (2 percent), but the Central and Eastern States decreased 7,758 tons (3 percent) and 22,906 tons (11 percent), respectively. The Tri-State area (Joplin region) maintained its position as the principal zinc-producing district, with 26 percent of the total United States output, even though production declined 5 percent in 1944. To an appreciable extent, this decrease can be attributed to the over-all labor shortage, but the main factor was a continuing depletion of high- and medium-grade ore reserves—particularly in the Oklahoma portion of the area. Nevertheless Oklahoma continued to be the principal zinc-producing State in the country, contributing 43 percent of the yield from the Central States, but only by the narrow margin of 77 tons above the production from Idaho. Output from the Eastern States decreased 11 percent, largely owing to a decided drop in production from New Jersey which, as a result, took third place in the United States.

The Western States supplied 46 percent of the domestic total output of zinc (43 percent in 1943) despite a drop in production from 5 of the 10 States. Idaho again was the largest producer. For the first time in the mining history of the State the quantity of zinc produced, which advanced 5 percent, exceeded the lead output, principally as the result of the large production from the Bunker Hill slag-fuming plant at Kellogg. New Mexico ranked second among the Western States despite a decline in output. Of the total 1944 production from this State, 88 percent was from the Central district. Colorado took third place over Utah by a narrow margin, both States showing a substantial drop in output. Half of Colorado's production of zinc came from the Eagle mine of the New Jersey Zinc Co., Empire Zinc Division, at Gilman, and 10 properties in Utah contributed nearly the entire State total output in 1944. About two-thirds of Montana's production was recovered at the East Helena slag-fuming plant of the Anaconda Copper Mining Co. The output of zinc from Arizona rose markedly in 1944 to 48 percent above the previous record of 1943; approximately 45 percent came from the Copper Queen and San Xavier mines. Additional data on production by mines and districts can be found in the State chapters.

STOCKS

PRODUCERS' STOCKS

Inventories of slab zinc at producers' plants continued to increase in 1944 and by December 31 were 37 percent above the previous year-end record total attained in 1943. All of the gain was at the primary reduction plants, as stocks at secondary distilling plants, although comparatively small, decreased 64 percent. Of the 233,696 tons on hand at the end of the year, 159,489 tons were Special High Grade and Regular High Grade, and the remainder (74,207 tons) was of lower grades, compared with 98,248 tons and 72,358 tons, respectively, at the end of 1943. The entire inventory gain can be accounted for by the accumulation of high-grade zinc, and the total represents 2½ months' requirements upon the basis of 823,598 tons shipped in 1944.

According to the American Zinc Institute, stocks of slab zinc followed a constant upward trend in 1944 until the high point was reached at the end of November. A subsequent drop by the end of December indicated a possible change in the trend, which was borne out by a continuation of the decline during the first 4 months of 1945.

Stocks of zinc on hand at zinc-reduction plants in the United States at end of year, 1940-44, in short tons

	1940	1941	1942	1943 ¹	1944
At primary reduction plants	19,212	24,212	82,498	168,777	233,044
At secondary distilling plants	761	890	1,942	1,829	652
	19,973	25,102	84,440	170,606	233,696

¹ Revised figures.

Stocks of zinc ore (60 percent concentrates) in the Tri-State district (as reported by the Tri-State Zinc and Lead Ore Producers' Association) on January 1, 1944, were 5,315 tons. The trend during the following 9 months was upward, the high point of the year (reported weekly) being reached on September 23 with a total of 12,770 tons. For the remainder of 1944, stocks showed a general decrease, descending to a low of 4,090 tons on December 2 and closing on December 30

at 4,664 tons. The accumulation of inventories was largely the result of reluctance on the part of the smelters of Tri-State concentrates to accept all such concentrates offered because of the narrowing margin between the rising cost of treatment and the ceiling price for slab zinc produced. In order to maintain a maximum possible production of zinc and prevent excess stock-piling of Tri-State concentrates, the Metals Reserve Company, acting upon a recommendation by the War Production Board, gave financial assistance to Tri-State smelters in the form of special premium payments starting in July 1944. The decline in stocks during the latter part of the year was the belated, though desired, result of this action.

According to an American Zinc Institute survey, total stocks of domestic and foreign zinc ore and concentrates at primary zinc-reduction plants suitable for the production of zinc metal on December 31, 1944, totaled 734,506 tons averaging 54 percent zinc. This compares with 673,247 tons containing 54 percent zinc at the end of 1943.

CONSUMERS' STOCKS

Stocks of slab zinc at consumers' plants decreased markedly in 1944, the total on December 31 being 28 percent below the quantity on hand at the beginning of the year. Inventories decreased rapidly from the high point at the first of the year to about 68,000 tons on March 31, advanced to 79,000 tons by the end of May, and in the following months showed a downward trend, with only minor fluctuations. The reason for the decided drop in stocks was the premature lowering of military requirements for zinc—particularly in the manufacture of brass—in expectation of an end to the European phase of the war in the fall of 1944. The 49-percent drop in slab zinc inventories at brass mills, ingot makers, and foundries reflects this situation. Stocks at zinc-rolling mills advanced 88 percent, the only one of the industry groups to show an increase. At the average monthly rate of consumption in 1944, consumers' stocks on hand at the end of 1944 were less than 1 month's requirements.

In addition to physical stocks on hand at consumers' plants at year's end, 19,000 tons of zinc were in transit to consumers, held for redistillation and in dealers' hands. Exclusive of an indeterminate quantity in bonded warehouses, the approximate total slab zinc in stock (including company- and Government-owned stocks at producers' plants) on December 31, 1944, was 318,000 tons. The comparative figure at the end of 1943 was 277,000 tons.

Consumers' stocks of slab zinc at plants at the beginning and end of 1944, by industries, in short tons

DOMESTIC CONSUMPTION

NEW SUPPLY

The following table shows the 5-year trend of primary slab zinc available for consumption in the United States. This calculated quantity, in effect, is equivalent to the primary slab zinc apparently made available each year for shipment to domestic consumers during the year.

In addition to primary slab zinc, 50,214 tons of redistilled secondary slab zinc were made available to consumers in 1944 after allowance for a decrease in stocks at secondary smelters. Also 7,741 tons of remelt spelter were produced from purchased scrap.

¹ Adjusted to exclude imported slab zinc further refined into high-grade metal in the United States.

CONSUMPTION

According to reports from 690 plants, representing an estimated 98 percent of the consuming industry in the United States, a record total of 888,626 tons of slab zinc (including 6,982 tons of purchased remelt spelter) were put in process in 1944. The 881,644 tons of slab zinc, excluding the remelt spelter, was 8 percent above the comparable total of 816,777 tons in 1943. Complete data showing consumption of remelt spelter in 1943 were not available. Receipts during 1944 were 863,135 tons. The apparent discrepancy between this figure and the calculated 902,963 tons of primary and secondary slab zinc and remelt spelter shipped to domestic consumers in 1944 can be attributed to incomplete coverage of the survey, receipts by dealers not included in the survey, variations in the quantity of metal in transit from producer to consumer at the beginning and end of the year, and unaccounted-for slab zinc stored in bonded warehouses.

¹ Based on a canvass of 600 plants in 1940, 1941, and 1942 and a somewhat larger coverage in 1943 and 1944, mostly from small consumers.

² Includes zinc used in electrogalvanizing, but excludes sherardizing.

³ Data on products according to industry not obtained for 1940.

⁴ Separate figures not available but included in total.

⁵ Includes miscellaneous articles not elsewhere mentioned.

⁶ Revised figures.

⁷ Included under "Other uses" in 1941 and 1942.

⁸ Included under "Zinc-base alloy" in 1943 and 1944.

⁹ Includes zinc used in making zinc dust, bronze powder, alloys, chemicals, castings, and miscellaneous uses not elsewhere mentioned.

¹⁰ Includes 6,982 tons of remelt zinc.

The result of partial relaxation of Government control over zinc in 1944 is indicated by certain comparisons of the 1944 data given in the above table with those for 1943. The quantity of zinc used for galvanizing showed a sharp increase of 25 percent, principally as the result of the larger supply of zinc and steel made available for the manufacture of products for civilian use. Zinc consumed in making brass products was 9 percent less than in 1943 because of cutbacks in military orders for cartridge brass. The manufacture of zinc-base alloy increased 11 percent, and zinc for French-process oxide rose sharply to 76 percent above the total for 1943 owing to the need for increased quantities of oxide for military uses.

Zinc for rolled products showed a marked rise of 58 percent in 1944 owing to relaxation of conservation measures. In addition to slab zinc, the rolling mills remelt and reroll the metallic scrap produced

from their fabricating operations. The scrap so treated in 1944 amounted to 21,555 tons—a 68-percent increase from the comparable total processed in 1943. Purchased zinc scrap in the form of zinc clippings, old zinc scrap, and engravers' plates totaling 1,786 tons were melted and rolled in 1944 (811 tons in 1943). The zinc lost in waste products, such as skimmings and ashes, totaled 1,999 tons in 1944, equivalent to 2.6 percent of the net production of rolled zinc. Production of rolled zinc from slab zinc and purchased scrap (including 74 tons of purchased remelt spelter) was 76,489 tons, an increase of 59 percent over the total for 1943. The total value of the rolled products was 65 percent more than in 1943 owing to a slight increase in the average price from \$0.120 in 1943 to \$0.124 in 1944. Inventories of rolled zinc were 1,711 tons on December 31, 1944, compared with 1,359 tons (revised figure) on the same date in 1943. In addition to the actual shipments of 48,503 tons of rolled zinc in 1944, the rolling mills processed 49,189 tons of rolled zinc (including that which was remelted and rerolled) in the manufacture of 27,634 tons of semifabricated and finished products.

Rolled zinc produced and quantity available for consumption in the United States, 1943-44

¹ Figures represent net production. In addition, 12,809 tons of strip and ribbon zinc in 1943 and 21,555 tons in 1944 were rerolled from scrap originating in fabricating plants in connection with zinc rolling mills.

² Less than 1 ton.

³ Allowances made for change in producers' stocks of rolled zinc.

The following table shows the six commercial grades of refined slab zinc and purchased remelt spelter consumed by the various industries in 1944. Of the 888,626 tons of domestic and foreign zinc consumed, 35 percent was Prime Western, 27 percent Special High Grade, and 24 percent Regular High Grade. All grades of zinc were used for galvanizing and in brass manufacture. Prime Western was the principal grade used in the hot-dip process of galvanizing, the higher

grades—largely in the form of anodes—being used chiefly for electro-galvanizing. Rigid specifications in brass manufacture necessitate the use of high-purity metal, 78 percent of the total used in this industry being of the two highest grades.

PRICES

The base ceiling price of 8.25 cents a pound for Prime Western grade slab zinc at St. Louis and \$55.28 per ton of 60-percent zinc concentrates at Joplin remained unchanged throughout the year. In comparison, the weighted average price received by the zinc producers for all grades of zinc sold in 1944 was 8.6 cents a pound, f. o. b. plants, the same as in 1943. The 1944 price of 11.4 cents for zinc, which appears in the State chapters, represents the above weighted average price received for slab zinc plus the increment—in terms of cents per pound based upon the total mine output of recoverable zinc—of \$39,908,642 paid by the Metals Reserve Company in 1944 in over-quota A, B, and C premiums and under special mine and smelter contracts.

The premium-price plan, whereby producers (miners) of zinc (copper and lead were also included in the plan) receive additional increments above the ceiling price (through Metals Reserve Company) for overquota production, was maintained throughout 1944. As the plan is operative only until July 31, 1945, Congress passed the Hayden-McFarland Bill, S-502, on June 14, 1945, thereby extending the time limit to June 30, 1946. More complete details of the scope of the premium-price plan—which was effective February 1, 1942—can be found in the chapter on Zinc in the Minerals Yearbook of 1942 and 1943. In May 1945 the Office of Price Administration released a comprehensive compilation of data showing production of copper, lead, and zinc under the premium-price plan since February 1942, at the various quota levels and the payments made. In addition, details of payments under special mine and smelter contracts for zinc were given. The salient statistics from this report with reference to zinc are shown in the following table:

American Metal Market quotes average prices of High Grade and Brass Special as follows: High Grade (f. o. b. New York)—1940, 7.38 cents; 1941, 8.48 cents; 1942, 9.25 cents (delivered); 1943, 9.25 cents (delivered); 1944, 9.25 cents (delivered). Brass Special (f. o. b. East St. Louis)—1940, 6.44 cents; 1941, 7.68 cents; 1942, 8.50 cents; 1943, 8.50 cents; 1944, 8.50 cents.

¹ Does not include overquota premium payments made by Metals Reserve Company.

ZINC-REDUCTION PLANTS**ZINC SMELTERS**

There was no change in the number of zinc smelters in 1944. For the past 4 years there have been 17 active commercial plants, of which 13 operated with horizontal retorts exclusively, 1 with both horizontal and vertical retorts, 2 with large vertical retorts exclusively, and 1 with electrothermic furnaces. The total number of retorts reported at the horizontal-retort primary plants was 71,912, a decrease of 1 percent from the 72,712 at these plants on December 31, 1943. Of the total retorts reported, 52,000 were in use at the close of 1944, a decline of 24 percent from the 68,232 in operation at the end of 1943. This marked decline was due entirely to the critical shortage of labor, which necessitated suspending operation of several blocks of retorts at each plant. Only 72 percent of the total retorts available in the United States was in operation at the end of 1944 as compared with 94 percent at the close of 1943. Of the 66 vertical retorts in the United States, 61 were in operation on December 31, 1944.

Eight primary plants in 1944 (9 in 1943) produced zinc from zinc scrap and residues such as zinc skimmings and dross. In addition to the 17 primary smelters, 9 plants (11 in 1943) produced redistilled secondary slab zinc by treating scrap zinc and other secondary zinc-bearing materials in clay retorts, graphite crucibles, and 2 special furnace installations. These 9 plants reported a total of 2,552 retorts and 91 crucibles on December 31, 1944, of which 1,320 retorts and 37 crucibles were in operation. Part of the available production capacity at secondary plants was used to produce zinc dust and zinc oxide in addition to slab zinc.

The St. Joseph Lead Co. continued experimental operation of its slag-fuming plant at Herculaneum, Mo., in 1944 for the recovery of slab zinc as a direct product of the operation which treats lead blast-furnace slag containing 12 to 16 percent zinc. Descriptions of the process² and the unique type of vacuum condenser used³ were published in 1944.

ELECTROLYTIC PLANTS

Five electrolytic plants were in operation during 1944, the same as in 1943, but only 2 produced at capacity throughout the year. There were 3,210 cells at the plants on December 31, 1944, of which 2,994 (93 percent) were in operation. No new installations were reported under construction or planned. A detailed description of the newest plant, built in 1942 by the American Smelting & Refining Co. at Corpus Christi, Tex., was published in 1944.⁴

FOREIGN TRADE⁵**IMPORTS**

During 1944 imports of zinc continued at a high rate, but the total in ore and as slab zinc was 18 percent below the record established in 1943. Of the 422,700 tons of zinc imported in ore, 42 percent

² Isbell, W. T., and Long, Carleton C., Direct Production of Metallic Zinc from Lead Blast-furnace Slag: Trans. Am. Inst. Min. and Met. Eng., vol. 159, 1944, pp. 176-181.

⁵ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

came from Mexico, 27 percent from Canada, and 10 percent each from Peru and Australia. Receipts from Mexico and Canada continued to gain, but imports of ore from Australia were down to a third of the 1943 total. The quantity from Argentina, another source of large tonnage in 1943, was also markedly lower. The principal reason for the decline from Argentina and Australia was that the large stock piles of ore that furnished the greater part of the record exports to the United States in 1943, for the most part, were depleted during that year, and shipments in 1944 came chiefly from current production. The substantial gain in imports of ore from Peru reflected the increased activity in zinc mining in that country. Imports of slab zinc continued to increase in 1944, despite a lower tonnage from Mexico, largely owing to a 111-percent gain in receipts from Canada.

² In addition, manufactures of zinc imported as follows—1940: \$32; 1941: \$1,099; 1942: \$16; 1943: \$35,355; 1944: \$14,223.

³ Less than 1 ton.

EXPORTS

The value of exports of zinc ore (and concentrates) and manufactured articles containing zinc of foreign and domestic origin (excluding galvanized products, alloys, and pigments) amounted to \$4,857,365 in 1944 compared with \$19,322,462 in 1943. Slabs, plates, or blocks continued to be the largest export group, but the total shipped to foreign countries decreased 78 percent—from 97,439 tons in 1943 to 21,576 tons in 1944. In addition to the items shown in the accompanying tables, considerable zinc is exported each year in brass, pigments, chemicals, and galvanized iron and steel. Export data on zinc pigments and chemicals are given in this volume in the chapter on Lead and Zinc Pigments and Zinc Salts. Much of the zinc used in the manufacture of such products is of foreign origin, and when they are exported a draw-back of 99 percent of the import duty is refunded upon the basis of zinc contained in the finished product. Data covering draw-back in 1943 and 1944 are not yet available. Draw-back payments were made on 23,047 tons in 1942.

WORLD ASPECTS OF THE ZINC INDUSTRY

The rapid succession of events in 1944 and 1945, culminating in the unconditional surrender of Germany in May 1945, paved the way toward revealing greater detail regarding the zinc industry in foreign countries than had been available since 1939. Censorship restrictions have been removed by the governments of most of the zinc-producing countries, and unrestricted information relative to the zinc industry in European countries formerly under Axis control is beginning to flow by way of official channels. It is not possible, however, to present with any accuracy the picture of world production and consumption of zinc during the years of the European phase of the war. The United Nations had ample supplies of zinc to meet all war requirements and most of the essential civilian needs in 1944. Total production of slab zinc from the United States, Canada, and Mexico, which represents more than half the world output, was less in 1944 than in 1943, and output from European smelters can hardly have increased under conditions existing in 1944, if for no other reasons than lack of ore, fuel, and adequate transportation facilities. In the face of an indicated decrease in world production, the maintenance of consumption at a high level could have been made possible only at the expense of accumulated stocks.

*World smelter production of zinc, 1938-44, by countries where smelted, in metric tons*¹

¹ Statistical data derived in part from American Bureau of Metal Statistics, Yearbook.

² Includes 3,670 tons of electrolytic zinc in 1938. Data not available for later years. Production of electrolytic zinc began in August 1935.

³ Estimate.

⁴ Data not available.

⁵ Included with Germany.

⁶ Some secondary metal included.

⁷ Includes Czechoslovakia.

⁸ Estimate included in total.

⁹ January to June, inclusive.

REVIEW BY COUNTRIES

Argentina.—Production of zinc concentrate in 1944 was 38,588 metric tons, an increase of 4 percent from the 37,185-ton output in 1943. The concentrate, nearly all of which is from the Aguilar mine, has averaged 54 percent zinc. Output of electrolytic zinc totaled

1,500 metric tons from a small plant at Uriburu, in the Province of Buenos Aires. Production in 1943 was 900 tons.

Australia.—The problem of obtaining sufficient manpower continued in 1944, but a reduction in the amount of ore treated by the Zinc Corp., Ltd.—due to labor shortage—was somewhat counterbalanced by an improvement in the grade. Although exploration and development has been curtailed to release labor to meet production requirements, the ore reserves have remained at roughly 4,000,000 long tons, averaging 11.5 percent zinc and 14.3 percent lead. The zinc content of concentrate produced in 1944 is reported to have been 50,361 short tons as compared to 49,959 tons in 1943.

Mount Isa Mines, Ltd., is reported to have 8,000,000 long tons of lead-zinc ore in reserve, containing 8.6 percent lead and 8 percent zinc.

Production data are being released by the Australian authorities but official figures had not been received at the time of writing (June 1945). Data from an unofficial source indicate that total mine production of zinc (recoverable zinc content of concentrates) in Australia was 150,800 short tons in 1944 (159,000 tons in 1943).

Belgium.—One of the paramount questions confronting the zinc industry—the status of the Belgian smelting industry and condition of the zinc plants during the German occupation of that country and subsequent to their retreat in the fall of 1944—has been answered. Although complete details are not available, it is understood that the smelters are substantially intact, having escaped serious damage by military operations or deliberate destruction by the retreating Germans. Production during the period of German occupation was but a fraction of capacity, and the resulting deterioration from several years of nearly complete idleness will necessitate considerable rehabilitation before full-scale operations can be resumed. Such repair work should not take many months providing adequate materials are available, but the principal draw-backs to resumption of operations at an early date are lack of fuel and concentrates and adequate transportation facilities.

Bolivia.—Mine production of zinc in Bolivia decreased from 21,074 metric tons (zinc content in ore and concentrate) in 1943 to 16,319 tons in 1944, mostly from the Huanchaca mine. The Matilde mine near Lake Titicaca, owned by the Compania Hochschild, was reported to have—as of 1944—some 4,000,000 metric tons of ore in reserve, containing an average of 18.7 percent zinc and 2.5 percent lead, 0.7 percent copper, and 1.75 ounces of silver per ton.

Burma.—The famous, centuries-old, Bawdwin lead-zinc mine—which before the war produced 40,000–50,000 tons of zinc in concentrate a year—was reported recaptured from the Japanese early in 1945. Not long before the recovery of the mine, the property was bombed by the Allies. As the ore reserves, as last reported before the war, indicated a relatively short remaining life, doubts have been expressed as to its being reopened if damage is found to be severe.

Canada.—Mine production of zinc in Canada in 1944 amounted to 264,667 short tons (preliminary), a decrease of 13 percent from the 305,377-ton output in 1943. Refined zinc production was 169,684 tons (preliminary) compared with 206,510 tons in 1943. Of the total output (all electrolytic), 70 percent was produced by the Consolidated Mining & Smelting Co., at Trail, British Columbia, and 30 percent by the Hudson Bay Mining & Smelting Co., Ltd., at Flin Flon, Manitoba.

The 250-ton mill of the Aldermac Mining Corp. at Sherbrooke, Quebec (reported in 1943 to be planned) went into operation in July 1944. The ore treated averages 7 percent zinc, 2.5 percent copper, 2 percent lead, and some gold and silver. The Normetal Mining Corp. increased production in 1944 under a contract for sale of the bulk of the zinc concentrates to the United States Government. The Zincton Mines, Ltd.—operating a 200-ton-a-day mill—continued production throughout 1944. In July the Department of Munitions and Supply announced that the Twin "J" mines, Duncan, British Columbia, Kootenay-Florence mine, Ainsworth, British Columbia, Lake Geneva mine, Benny Siding, Ontario, and Tetreault mines, Notre Dame des Anges, Quebec, had suspended operations. These four high-cost lead-zinc properties had produced under contract for the United States Metals Reserve Company. It was reported that existing contracts between principal Canadian producers and the British Government were renewed for 1 year from September 1, all contracts being terminable—should the war end—on 3 months' notification. At the end of 1944 the Hudson Bay Mining & Smelting Co., Ltd., had 531,000 tons of zinc-plant residues in storage. Some progress had been made in developing a process for treatment, but a satisfactory recovery method applicable to the recovery of all contained metals had not yet been found.

France.—The zinc-smelting industry in France depends largely on imported ores, but beginning in 1941 increased quantities of zinc concentrates were produced in France, partly from mixed lead-zinc ores, and from the Pierrefitte zinc mine in the Pyrénées. However, the entire output amounts to less than 5 percent of prewar domestic requirements. Mine production of zinc (content of zinc in ores and concentrates) from 1938 through 1944, in metric tons, was as follows:

Year	1938	1939	1940	1941	1942	1943	1944
Production.....	95	500	1,420	3,055	3,215	2,648	2,387

Until shipping is available for imports of lower-cost zinc concentrates, most of the zinc smelters in France will remain idle, and the country will depend on imports of zinc metal for its most urgent requirements.

French Morocco.—Production of zinc from 1940 through 1944 was as follows (data in metric tons):

Year	1940	1941	1942	1943	1944
Ore and concentrates.....	4,553	1,142	1,484	976	2,229
Zinc content.....	2,276	721	742	488	1,137

Mexico.—Production of zinc in Mexico continued to advance, despite many unfavorable conditions, the total output—in terms of zinc in exportable ore plus smelter production—amounting to 219,309 metric tons compared with 197,199 tons in 1943. A general labor strike against some 140 mining and smelting companies was called on June 8 and was not completely settled until August 11. Severe floods in the fall of 1944 further complicated the problem of transportation,

already critical by virtue of a shortage of railway cars and run-down condition of the railway system.

Newfoundland.—Mine production of zinc, in terms of zinc content of all concentrates produced, amounted to 59,472 short tons compared with 66,418 tons in 1943. This tonnage was from 98,813 tons of 53-percent zinc concentrate (108,642 tons in 1943) and includes 7,542 tons of zinc contained in lead and copper concentrates (8,874 tons in 1943).

Peru.—The zinc content of concentrates produced in Peru during 1944 has been estimated to total 56,263 metric tons compared with 31,347 tons in 1943. This estimate is based upon reports of the major zinc-producing companies, of which group the largest is the Cerro de Pasco Copper Corp. The 800-ton daily capacity concentrating plant of this company, which started production late in October 1943, operated throughout 1944 on copper ore. The plant was built primarily for the treatment of lead-zinc ores in connection with a projected commercial-scale electrolytic zinc plant which has not yet been constructed. The electrolytic zinc pilot plant operated by the company produced 1,441 metric tons of zinc in 1944.

The tailings plant of Cia Minera Atacocha, S. A., Department of Junin, was finally completed in the summer of 1944. The zinc concentrates from the tailings and the mine make this company one of the principal producers in Peru. Atacocha produced 58,200 metric tons of ore in 1944, averaging 14 percent zinc and 13.5 percent lead. By the end of 1944 the Volcan Mines was producing at the rate of 11,000 short tons a month. Production for the year was 66,677 short tons, averaging 17.65 percent zinc and 7.79 percent lead. The ore is milled under contract at the Mahr concentrator of Cerro de Pasco Copper Corp.

The Over-All Metals Agreement between the Peruvian Government and the United States Commercial Company was renewed August 8, 1944, effective as of July 1, 1944, when the previous agreement expired. The agreement provides for the purchase of zinc ores and concentrates. On December 6 the Peruvian Government was officially notified of an intended revision with respect to quantity and prices of metals and minerals to be purchased. Under the revision, the price of zinc in ores and concentrates (zinc content 55 percent or more) was reduced from 6 to 5 cents a pound f. o. b. steamer at Mollendo or Callao, less usual commercial smelting and treatment charges and deductions for metal losses and impurities.

Spain.—Output of zinc concentrates in 1944 was reported to be 57,590 metric tons (72,349 tons in 1943) and slab zinc 18,048 tons (19,200 tons in 1943). The lower output of concentrates was in part due to the interruption of traffic with Germany. The Reocin mine of Real Asturiana, which produced 80 percent of the total zinc concentrates, has large ore reserves and plans to expand production when equipment and power become available. The Arnao zinc smelter of this company produces all the zinc currently consumed in Spain. It is expected that the output of zinc will increase in the future and will be available for export as concentrates unless the domestic zinc smelter capacity is increased.

Sweden.—Zinc refining, from ore, was resumed in 1944 at the Trollhattan plant, at the rate of 5,000 metric tons a year. Restrictions on zinc were withdrawn in May 1944 as available supplies equaled the annual consumption level of 15,000 tons.

LEAD AND ZINC PIGMENTS AND ZINC SALTS

GENERAL SUMMARY

Further improvement in sales of lead and zinc pigments was evident in 1944 over the generally low performance of this group in 1942. Conditions that applied to the earlier war years continued in 1944. In large part these conditions included outstanding war requirements for many items and shortages of essential crude materials and of manpower. For several years sales of the various pigments have not indicated actual demands for any of the items, because all the pigments have been influenced by manpower shortages and all have been affected in varying degree by shortages of necessary primary and subsidiary crude materials. The crude materials used for certain pigments have been in more abundant supply than for others; as a result, during the war some pigments have benefited—temporarily at least—at the expense of others. In 1944 war needs took a preponderant share of total sales of pigments, with the proportion increasing over the earlier war years. Pigments manufacturers continued to be hampered by restrictions on supplies of linseed and other drying oils and of slab zinc, and by limitations on containers. At the end of the year consumers of lead for the manufacture of pigments for civilian requirements faced sharp cuts in the quantities of this metal that could be used. Late in 1944 it was announced that, effective January 1, 1945, the quantities of fats and oils for use in the manufacture of protective coatings, coated fabrics, and floor coverings for civilian consumption were to be reduced from 70 to 60 percent of the average quantities for 1940 and 1941. For over a year, producers had been trying to build their civilian accounts as a safeguard against prospective cancellation of war orders, but these efforts did not come to fruition in 1944. Late in the year supplies of paint, varnish, and lacquer materials were bolstered by limited releases of surplus stocks

by some branches of the Government. As the year ended, however, war demands as a whole did not indicate that they had reached their maximum.

As in 1943, paint, varnish, and lacquer sales were at a new high record rate; the 1944 total was 9 percent above the former record. These data, compiled by the United States Department of Commerce, cover 680 establishments that contributed approximately 90 percent of the total value of the industry as reported in the Census of Manufactures for 1939. The value of sales totaled \$618,325,532 in 1944 compared with \$568,620,999 in 1943.

Trends in the supply-requirements positions for lead and zinc, as indicated in the chapter of this series for 1943, continued in 1944. These trends were toward larger supplies in relation to requirements for zinc and toward more stringent supplies of lead. This situation is explained, in part, by the fact that lead is a less-obvious war metal than zinc. As a consequence, more generous allowances of this metal had been made available for civilian use, and in addition encouragement had been given in the early part of the war to substitution of lead for some metals in relatively smaller supply. Improvement in the zinc situation continued into the third quarter of 1944, and this movement was accompanied by a tendency to lessen the restrictions on zinc. Meanwhile, despite the fact that stocks of lead dropped severely in 1944, ample supplies of metal were available to pigment makers until late in the year. The fourth quarter of 1944, which brought military disappointments, caused an abrupt revision of Government viewpoint regarding war requirements, called for larger war orders along many lines, and removed ideas of further allocations for civilian requirements. Not only were all moves toward greater allowances of zinc discontinued, but controls on lead were strengthened markedly by a revision of War Production Board Order M-38 in December and by further revision in January 1945. The revised lead order and other orders that affect the pigments covered by this report are discussed later.

Record-breaking production and sales of titanium pigments, which normally compete for markets supplied by lead and zinc pigments, were established in 1944, but even the increased amounts made available fell far short of supplying all requirements for expanded war and civilian needs. The Bureau of Mines is not at liberty to publish figures covering pigments of this class. The titanium group was subject throughout 1944 to the restrictions of Order M-353.

The feature of sales of lead and zinc pigments in 1944 was the high record quantities of litharge and red lead sold for battery manufacture. As a consequence of this outstanding consumption, both litharge and red lead established new high rates of sales in 1944—red lead by a narrow margin only because of a decline in sales for paint. The feature for 1943 was the large amount of zinc oxide sold for chemical warfare purposes. Sales for this use rose from none in 1942 to 22,000 in 1943, and continued upward to 28,000 tons in 1944. Increases of 13,500 tons in white lead and of 20,000 tons in leaded zinc oxide sold for paint in 1944, plus smaller gains for lithopone and basic lead sulfate, much more than offset the declines in red lead and zinc oxide sold for this purpose and reflected the record sales of paint, varnish, and lacquer materials in that year. Agricultural use of litharge reached a new high level in 1944 for the second year in succession. So far as

it is possible to ascertain, sales of zinc sulfate for agricultural purposes were also at a new record rate in 1944. For the most part, sales of pigments for the manufacture of ceramics rebounded somewhat from the low rates that prevailed in 1942 and 1943, but white lead did not share in the gains. Use of zinc oxide in the manufacture of rubber receded in 1944 from the relatively favorable rate that prevailed in 1943; distribution of litharge for this purpose, which had been gaining in recent years, also declined.

Two articles¹ concerning experiments in connection with war uses of paints were recently published. The Bureau of Standards² issued a report which is the third and last of the series covering the investigation of pretreatments and paints for protecting plain and galvanized steel surfaces against corrosion.

Salient statistics of the lead and zinc pigments industry of the United States, 1939-44

	1939	1940	1941	1942	1943	1944
Production (sales) of principal pigments:

WAR AGENCY REGULATIONS

Lead was subject throughout the year to the limitations imposed by War Production Board Order M-38. This order was strengthened markedly in December by revisions that were expected to reduce civilian consumption to about 60 percent of the 1944 rate. A further revision on January 15, 1945, placed the lead pigments covered by this report (except litharge for storage-battery manufacture which remained under Order M-38) under a new chemicals order, M-384.

¹ Journal of the Franklin Institute, Exterior Paint on Temporary Army Buildings: Vol. 238, No. 6, December 1944, p. 455.

The Paint Industry Magazine, Paint, Its Durability and Use Under Field Conditions: Vol. 60, No. 1, January 1945, pp. 18 and 20.

² National Bureau of Standards, Building Materials and Structures, Painting Steel: Rept. BMS102, Oct. 16, 1944.

The sweeping M-384 order restricted the quantities of lead that could be put into process in any calendar quarter for the manufacture of basic carbonate of white lead to not more than 15 percent of that put into process in the first 6 months of 1944, and for leaded zinc oxide to 25 percent of the white lead (not lead content) put into process during the entire year 1944. Lead used in various products, such as insecticides, was similarly affected. The red lead that could be put into process in any calendar quarter in the production of paints, varnishes, and lacquers (including paste red lead) for civilian uses was limited to not more than 30 percent of the amount of pigment (not the lead content) similarly used in the first 6 months of 1944. The white lead that could be put into process in any calendar quarter for the foregoing purposes (including paste white lead) was restricted to 8 percent of the quantity of white lead (not the lead content) used in the base period. Ceramics manufacture for civilian uses was limited to 25 percent of the amounts of lead consumed in the base period. In each case there was the option to use 1,000 pounds per quarter if that quantity were greater than the stated measure. The order also placed inventory restrictions on white-lead consumers who were covered by it. White lead is defined in the order as meaning either basic carbonate of white lead or basic sulfate of white lead.

Zinc metal is controlled by War Production Board Orders M-11 and M-11-b. Consumption restrictions on zinc were liberalized during the year, as was indicated in the summary section of this report, but the tendency to ease the covering orders disappeared following military disappointments in the fall of 1944. Zinc oxide (lead-free) is subject to Order M-11-a, which was amended June 16 to add laboratory reagent chemicals, cellulose nitrate plastics, vulcanized fiber, and toilet soap to the list of permitted uses. The revised order also specified the type of paint in which lead-free oxide could be used. Leaded zinc oxide, which had escaped control until then, was placed under Order M-11-a in an amendment dated February 17, 1945. Order M-128, which referred to zinc sulfide pigments but which had been inoperative, was revoked in June 1944. The titanium pigments order, M-353, was amended to include zinc sulfide pigments, effective July 1, 1944. Thus priority ratings of AA-2 or higher were required for the purchase of all of these pigments; lower ratings were ineffective, with the exception of material needed to fill orders for the armed services, in which case such orders had to be accompanied by the certification set forth in M-353. The last order was amended in November to provide that only those rated orders that are accompanied by military certification would be treated as valid and filled as preferred orders.

POSTWAR OUTLOOK

The inability of pigments manufacturers to increase the civilian share of their business in 1943 and 1944 probably merely raised the amounts of these products that will have to be supplied after the war. Trigg² stated that deferred maintenance jobs, most of which will require paint, have been estimated as high as \$30 billions. He said that he felt justified in predicting a rapidly expanding future for the paint, varnish, and lacquer industry because:

² Trigg, Ernest T., *After War—What?!*: Paint Industry Mag., vol. 59, No. 11, November 1944, pp. 368-370.

In the first place, we have no reconversion problems. With reasonably speedy victory over Germany already assured and with victory over Japan in much clearer prospect than seemed likely before Germany's impending collapse, we are fully equipped for a head start without necessity of awaiting the final victory in the Pacific theater of war, while many other industries will have to reconvert their factory operations and cannot get started in new production for a considerable time to come. However, no matter what other industries do, they will need our products for practically any activities in which they engage.

As civilian production gains headway in catching up with the great backlog of deferred civilian needs, the demands upon the paint industry may be expected to surpass the records achieved in the peak war years.

The expected gain in postwar production of automobiles until pent-up requirements are filled was outlined in the report of this series for 1943. This gain and increases in production of other civilian equipment retarded by the war will call for pigments for finishes, storage batteries, rubber, and other items that are large pigment users. Railroads will need large supplies of pigments, as pointed out by Trigg in the article already cited, to rehabilitate rolling stock, stations, bridges, and other properties and equipment. He indicated also that a large merchant marine and the biggest Navy in the world will provide a large postwar market for pigments. The pigments export market for the purposes itemized could provide a postwar outlet for very large tonnages.

There seems to be little question regarding the size of postwar requirements for pigments. The main question concerns the proportions of the market that different pigments will supply. In this connection, the prewar shifts from certain pigments to others are expected to continue in postwar years.

PRODUCTION

Previous reports of this series have indicated that sales are a better guide to activity in the pigments industry than production because complete data are not available on stocks and materials classified as production of one item are sometimes disposed of under another classification. Moreover, pigments produced under one classification at a plant are sometimes employed at a plant of another company for blending into another pigment in the lead and zinc group. The Bureau of Mines attempts to eliminate all possible duplication and to tabulate products only in the form in which they enter final use as pigments. Thus the quantities of basic lead sulfate and zinc oxide that are blended to make leaded zinc oxide are omitted, except as leaded zinc oxide. Duplication caused by other blending, which is on a considerably smaller scale, is also avoided insofar as possible. Pigments consumed by the producing companies, however, to make products beyond those covered by this report—that is, paint, storage batteries, and other articles—are considered as sales.

The value of lead and zinc pigments in 1944 totaled \$85,889,000, a gain of 10 percent over 1943; it was the largest since 1929 and exceeded 1941 by a narrow margin.

LEAD PIGMENTS

As in 1943, litharge and red lead made the best showings of the pigments covered by this report; sales of both items were at higher levels than ever before, being 22 and 1 percent, respectively, larger than in

1943 and 13 and less than 1 percent above the previous records established by both classes in 1941. White lead sales have not maintained the pace set by most other pigments. Although they gained 13 percent over 1943 they were far below the records for most earlier years since before 1900. In 1944 the value of lead pigments sold gained 11 percent over 1943 and were 44 percent above the annual average for the prewar period 1935-39. The zinc total, meanwhile, was larger by 8 and 46 percent, respectively. The average values received by producers for litharge and red lead were reduced in 1944 as compared with 1943. As there was no reduction in average unit quotations for these two classes of pigments, the declines must be explained by shifts in delivery points of portions of the sales. The producers' values refer to values at plants.

ZINC PIGMENTS AND SALTS

Leaded zinc oxide registered the largest percentage gain in 1944 of the pigments covered by this report, except for the small tonnage of orange mineral; sales of leaded zinc oxide increased 47 percent. Total sales of leaded zinc oxide in 1944 were exceeded only by the tonnage for 1941 and failed to equal that record by 7 percent. The quantity of zinc oxide (lead-free) sold had the largest percentage rise in 1943 (44 percent), but it declined 2 percent in 1944. Government control of this pigment during much of the war has tended to divert consumers to other pigments. Lithopone sales increased 5 percent in 1944, but the rate was not high as compared with most years between

1925 and 1941. Producers' average prices showed some variation in 1944 from 1943 levels, but these changes do not reflect revisions in average quoted prices.

¹ Data not available.

² Includes a small quantity containing less than 5 percent lead.

³ Satisfactory data not available.

Figures covering zinc chloride for 1944 are not available because of the refusal of one company, believed to be large, to give reliable data.

Sales of zinc sulfate failed by 11 percent to equal the rate for 1941, but except for that year they were the highest on record.

CONSUMPTION BY INDUSTRIES

WHITE LEAD

Sales of this pigment, which declined in 1943, returned virtually to the 1942 level in 1944. Total sales for the dry and "in oil" varieties increased 13 percent in 1944, but amounted to only 84 percent of the annual average for the prewar 5-year period, 1935-39; they were not much more than half of the average for the period of high industrial activity in 1925-29. The dry class gained 18 percent compared with 7 for the "in oil" grade, and it has fared much better, on the whole, for many years.

By far the largest part of white lead sales is for consumption in the manufacture of paints, ordinarily over 90 percent entering this use; 93 percent was reported as having gone into paints in 1944. It is believed that a break-down of the Other class would raise the paint total. Sales of white lead for the manufacture of ceramics declined in 1944 against the trend for other pigments used for that purpose.

Production of white lead totaled 76,191 tons in 1944.

Distribution of white lead (dry and in oil) sales, 1940-44, by industries, in short tons

Industry	1940	1941	1942	1943	1944

Total.....	4,396	8,631	4,990	8,282	4,832
	80,562	113,000	83,639	76,167	85,726

The Eagle-Picher Lead Co. commented on the difficult operating conditions in its report to stockholders, as follows:

The White Lead Division continues to face almost prohibitive operating conditions. Recent drastic reduction in the allocation of lead to the production of paint pigments, coupled with a long-standing limitation order on the use of linseed oil, has reduced the permitted production of this Division to a degree that definitely precludes any hope of profitable operation.

BASIC LEAD SULFATE

The chief use of this pigment is also in the manufacture of paint. Large quantities, likewise, are used annually as an intermediate step in the manufacture of leaded zinc oxide. The amount so used is not counted as finished basic lead sulfate but is covered in this report under the figures for leaded zinc oxide. As a component of leaded zinc oxide also it goes chiefly into paints. In 1944, 7,800 tons of basic lead sulfate were sold for use in the manufacture of leaded zinc oxide compared with 6,100 tons in 1943. Leaded zinc oxide makers reported having used 5,600 tons of basic lead sulfate in 1943; comparable data for 1944 are not available.

Production of basic lead sulfate totaled 4,605 tons in 1944.

RED LEAD

Trade in red lead was heavy in 1944, and a new high record total for sales was established by a narrow margin over 1941. This pigment has enjoyed great activity in the war years largely because of its desirability as a construction paint. The paint use, however, took 19 percent less red lead in 1944 than in 1943—its peak year thus far—and storage-battery manufacture, which regularly consumes the principal tonnages, took its turn at establishing a new high rate in its demand for red lead. Total red lead sales were less than 1 percent above the previous record in 1941, but sales for storage-battery manufacture rose 10 percent above the 1941 peak.

Production of red lead totaled 53,398 tons in 1944.

ORANGE MINERAL

There was a noteworthy gain in sales of this small-tonnage pigment in 1944. With the increase, the principal use changed from the manufacture of ink to the manufacture of color pigments. The advance in 1944 was made over the smallest annual total since 1889.

Production of orange mineral amounted to 280 tons in 1944 contrasted with only 3 in 1943.

LITHARGE

A new peak rate of sales of litharge for storage-battery manufacture in 1944 carried total sales of litharge to record heights; they were 22 percent higher than in 1943 and 13 percent above the previous peak in 1941, and they thus made the best showing of the pigments covered by this report. Battery manufacture took more than half of the total, a condition that has existed only once before, in 1932, since the Bureau of Mines began to collect data on distribution of sales; in 1932 total sales of litharge were only 80 percent of the amount sold for battery manufacture in 1944. In addition to the litharge used to make batteries, the storage-battery manufacturers themselves produce a black or suboxide of lead which they use as a substitute for litharge. The amount so used in 1944—61,000 tons—equaled the record tonnage for 1941 and was 1,000 tons above 1943. In 1944, 58,000 tons of pig lead were required to manufacture the suboxide, compared with 57,000 in 1943. Black oxide figures are not included in the Bureau of Mines totals for litharge. Insecticidal use of litharge also made a new high record for the second successive year in 1944, surpassing the previous peak of 1943 by 28 percent. Ceramics took 25 percent more litharge than in 1943. Other of the larger users of litharge, except oil refining, took less of the pigment in 1944 than in 1943, the decline for rubber contrasting with the uptrend of recent years. The drop in use in chrome chemicals is explained more by restricted allowances of chrome than of lead.

Production of litharge amounted to 146,900 tons in 1944 compared with 112,037 tons in 1943.

Distribution of litharge sales, 1940-44, by industries, in short tons

ZINC OXIDE

Sales of this pigment receded slightly in 1944 from the relatively favorable rate that prevailed in 1943, but owing to restrictions on its use the amount of sales in neither year can be taken as a guide to total consumption requirements. Consumption for chemical warfare purposes gained 27 percent over 1943 against the trend for rubber and paints, the other principal classes of use, and this use superseded paint as the second most important outlet. Zinc oxide used in the manufacture of rubber declined 12 percent, and that used for paint declined 16 percent. The decrease for rubber is explained by the smaller percentage use of zinc oxide for synthetic versus natural rubber. Leaded zinc oxide was taken for some paint needs where the lead-free grade would have been specified except for the restrictions thereon.

Production of lead-free oxide amounted to 152,366 tons compared with only 123,913 tons in 1943.

Distribution of zinc oxide sales, 1940-44, by industries, in short tons

LEADED ZINC OXIDE

Sales of leaded zinc oxide rose more sharply as compared with 1943 than any other pigment covered by this report; they gained 47 percent and were second only to the record tonnage for 1941, being 7 percent less than in that year. The preponderant use is in the manufacture of paints. This pigment was not subject to allocation control in 1944 as was the lead-free class, which resulted in its use in certain instances where the lead-free class would normally have been specified. It will be noted that sales of lead-free zinc oxide for the manufacture of paints declined 16 percent in 1944. The figures for leaded zinc oxide include basic lead sulfate used in blending, as is indicated under Basic Lead Sulfate.

Leaded zinc oxide production totaled 64,432 tons in 1944 compared with 39,515 tons in 1943. The totals are broken down as follows (1943 revised data in parentheses): Over 5-35 percent lead, 52,022 (33,144) tons; over 35-50 percent, 8,364 (5,908) tons; and most of the remainder in both years, 5 percent or less.

Distribution of leaded zinc oxide sales, 1940-44, by industries, in short tons

LITHOPONE

The lithopone statistics in this report are given on the basis of ordinary lithopone sold as such plus the ordinary lithopone content of the high-strength product. This method of publication is used to conceal the operations of one company which always dominates the output of the high-strength product and is the only producer in some years. In 1944 three companies, operating four plants, produced high-strength lithopone, but one company made a negligible contribution to the total. Lithopone sales in 1944 were influenced by the historic peak in total sales of all paint, varnish, and lacquer materials, over three-quarters of the sales of this product regularly going into paint, varnish, and lacquer channels. It is significant that lithopone sales for paints rose somewhat less than total sales of paints, varnish, and lacquer materials, inasmuch as lithopone would naturally benefit from restrictions on sales of other pigments, such as zinc oxide and titanium dioxide. Floor coverings and textiles take the next-most important amounts of lithopone, and sales for this purpose dropped 8 percent in 1944. A separation of the quantities for 1944, based on somewhat incomplete data, indicate that 9,578 tons were for floor coverings and 5,168 for coated fabrics and textiles. Use of lithopone for the manufacture of paper has been gaining and amounted to 6,488 tons in 1944, compared with 4,043 tons in 1943, 3,423 in 1942, and 5,559 in 1941. The 1944 total is a peak rate since 1937, the first year for which separate figures for this use are available. The consumption of titanium dioxide for paper manufacture was also at a high rate in 1944, the gross weight of titanium pigments showing a peak rate since before 1935 (the first year for which separation is available) but the TiO_2 content lagging behind that for 1943 and the even higher total for 1941. Printing ink took a large amount of lithopone (1,216 tons) in relation to most other years since before 1936 (the period for which data are available); the total for 1941 (2,301 tons), however, was considerably above all other years since before 1936. Exports are included mainly under Other, but one company at least classifies part of its exports according to the end use.

Plant capacity for the production of lithopone was reported to total 155,000 tons in 1944 or relatively the same as the 157,000 tons for 1943.

Production of lithopone totaled 133,960 tons compared with 132,621 tons in 1943. Stocks were reduced in both years. The plant of the

Lake and Pigment Department of the American Cyanamid Co. (formerly United Color & Pigment Co.) produced no lithopone in 1944, and no production is planned there for the future.

Distribution of lithopone sales, 1940-44, by industries, in short tons

¹ Includes a quantity, not separable, used for printing ink.

There was little change in consumption of ordinary-strength lithopone in the manufacture of titanated lithopone (which usually contains about 15 percent TiO_2), as 8,300 tons were used in 1944 compared with 8,400 in 1943. Production of titanated lithopone totaled 9,800 tons in both years. The lithopone figures in the following table are included in the totals for ordinary lithopone in the preceding table.

Titanated lithopone produced in the United States and ordinary lithopone used in its manufacture, 1940-44, in short tons

ZINC SULFIDE

Only one company produced zinc sulfide in 1944, as in 1943 and 1942, and the Bureau of Mines is not at liberty to publish figures for this pigment.

ZINC CHLORIDE

The Bureau of Mines is unable to publish figures on zinc chloride because of the refusal of one company, whose output is reported to be large, to give reliable information.

ZINC SULFATE

Sales of zinc sulfate increased 10 percent in 1944 and were second only to those for 1941, being 11 percent below that year. Rayon usually accounts for the largest part of sales of zinc sulfate, and this use stood first in 1944 with what appeared to be the largest quantities on record for one year. A more precise break-down of the "Chemical" class for 1941, however, might easily place 1941 sales for rayon above the 1944 total. The agricultural use of zinc sulfate has been growing in recent years, and the indication that this use took record quantities of zinc sulfate in 1944 seems likely to be true. Zinc sulfate finds varied application in agriculture. Some of the ways in which it is used are: As a fungicide in a variation of Bordeaux mixture in which

zinc sulfate is used in place of copper sulfate; with lime to spray peach trees for bacterial spots; more extensively with lime as a safener when arsenate of lead is used as a spray; with lime as a spray on various trees to make up for zinc deficiencies in the soil; alone directly in the soil to make up for zinc deficiencies; alone as a spray where the foliage will stand it; and to a certain extent for weed eradication. The sharp rise in sales of zinc sulfate for paint and varnish processing in 1943 was more than counteracted in 1944. The use of zinc sulfate for the manufacture of glue continued its substantial decline in 1944.

RAW MATERIALS USED IN MANUFACTURE OF LEAD AND ZINC PIGMENTS AND ZINC SALTS

Figures covering the raw materials used in making pigments and salts were not available when the report of this series for 1943 was prepared. Data for 1943 are given below, and those for 1944 will appear in a subsequent report.

Lead pigments and zinc pigments and salts are manufactured from a variety of materials, including ore, refined metal, and such secondary materials as scrap and waste from various industrial processes. In 1943, 93 percent of the lead in pigments was derived from pig lead and 7 percent from ore. Of the lead in ore used to make leaded zinc oxide, about 10 percent was from foreign sources. The proportion for zinc pigments in 1943 was 78 percent from ore, 8 percent from slab zinc, and 14 percent from secondary materials; about 14 percent of the ore used was foreign.

	² 225,574	142,996	218,307	144,113

¹ Includes also lead recovered in leaded zinc oxide.

² Revised figures.

³ Zinc ashes, skimmings, drosses, and old metal.

The following tables give the source of the metal used in the manufacture of each pigment and salt. Pig lead is employed exclusively, either directly or indirectly, in the manufacture of white lead, litharge, red lead, and orange mineral and is used also in the manufacture of basic lead sulfate. The lead content of leaded zinc oxide made from basic lead sulfate, which in turn was made from pig lead, is credited to pig lead in the table. Zinc oxide is the only pigment in which considerable slab zinc is used. Ore is employed in the manufacture of zinc oxide, leaded zinc oxide, lithopone, zinc sulfate, and basic lead sulfate. A substantial proportion of the zinc in lithopone and most of that in zinc chloride made in the United States are derived from secondary material. For a number of years before the United States entered World War II there had been a large increase in the quantity of secondary zinc used in the manufacture of zinc oxide. The scarcity of supplies of both metal and scrap caused the proportion of the total oxide made by the French process to drop sharply in 1942 and to continue low in 1943, despite the fact that the tonnages produced by that process rebounded somewhat in the latter year.

¹ These figures are higher than those shown in the report on Secondary Metals—Nonferrous because they include zinc recovered from byproduct sludges, residues, etc., not classified as purchased scrap material.

² Bureau of Mines not at liberty to publish.

PRICES

The total and average values reported by producers for lead and zinc pigments and zinc salts are given in the tables in the first part of this report. For most of the products covered there was little change in average prices received, but those for both red lead and litharge declined. The lower values for these two products can be explained only by variation in delivery points of portions of the total sales. Producers' values are reported on an f. o. b. plant basis. The ceiling prices established by the Office of Price Administration for the pigments and salts covered in this report, and likewise those for the metals lead and zinc were unchanged throughout 1944 at the levels that prevailed in 1943.

¹ Quotation was reduced to 3.65-4.40 cents per pound in the September 11 issue, which added "works", freight allowed," to the description.

FOREIGN TRADE⁴

The average annual value of foreign trade in lead and zinc pigments has remained relatively high during the war as compared with prewar levels. The principal trade is under the export classifications, no import item reaching \$30,000 in value in either 1943 or 1944. Lead pigments export values declined 4 percent in 1944 as compared with 1943 but were 142 percent above the average for the 5-year period 1935-39, whereas zinc export values declined 26 percent and were 275 percent above the prewar average. Total exports of both classes (lead and zinc pigments) in 1944, however, amounted to only 4 percent of the value of total production in the United States.

⁴ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

¹ Data not available.

Lead pigments and salts.—Imports of lead pigments are virtually nonexistent. White lead is the principal export item under this heading, with red lead and litharge following in order of importance among the pigments, and lead arsenate standing out among the salts. Shipments of white lead from the country declined 35 percent in 1944 following a comparatively high rate of exportation in 1943. Exports of all of the other items specified rose in 1944, but those for lead arsenate did not equal half of the 1941 rate.

Lead pigments and salts imported for consumption in the United States, 1940-44

¹ Not compiled on an annual basis before 1942.

Zinc pigments and salts.—Zinc sulfate is the principal import item under this class, but it amounted to only 542 tons in 1944, virtually the same as in 1943. Lithopone and zinc oxide are the principal products exported and their individual quantities largely exceed each of the lead classes. Exports were smaller in 1944 by 33 and 8 percent, respectively, and the virtually constant rates for 1943 and 1942 were below those for 1941. Principal zinc salts exported, shown separately on an annual basis for the first time in 1942, are zinc sulfate and zinc chloride. Available data are covered in the footnote to the second table that follows.

Zinc pigments and salts imported for consumption in the United States, 1940-44

THE MINERAL INDUSTRY OF ALASKA

(MINE REPORT)

By H. FOSTER BAIN

SUMMARY OUTLINE

	Page
General conditions.....	219
Metal production.....	222
Calculation of value.....	222
Nonmetallic production.....	226

GENERAL CONDITIONS

The demands for men and materials with which to wage World War II caused a major dislocation in Alaskan mining in 1944. The total value of the mineral output dropped to \$7,032,000,¹ substantially what it was at the beginning of this century. Gold mining, which has always been the leading mining industry, and which in 1906 yielded over a million ounces, decreased to approximately 50,000 ounces, the smallest yield since the historic discoveries of 1898. For the time being at least virtually all of the modern gold-mining industry, which has meant so much to Alaska, was wiped out, becoming a war casualty. Not all of this happened in 1944, but the nadir was reached in that year. The descent began early in the war when, in order to construct air bases, roads, and other war facilities, both men and equipment were moved almost bodily out of the mines and into the war-construction gangs. This was particularly upsetting to Alaskan economy as gold mining has long been the leading inland activity, and almost all of Alaskan industry away from the coast depends on the prosperity of the mines. It was a war sacrifice no State was called upon to make in like degree. It had, naturally, some compensations. The spending of great sums of money to create the new war facilities produced a flush of temporary prosperity, and some of the roads, air bases, and port facilities will be of permanent use. Not all will be permanent, as in the rush that the times demanded much temporary construction was necessary in some places, and some, perhaps, was not well-considered. Out of it all will have come a very great improvement in the facilities for communication and transportation which has long been among the most insistent needs of the Territory. This however does not alter the fact that the whole economy of the region was upset, and the reconstruction period is sure to be difficult and perhaps long.

The closing of the great Alaska Juneau mine—long famous as the world's greatest low-cost producer—which to the end of 1943 had added \$80,489,823 to the world's wealth in gold, silver, and lead, was a historic event of great magnitude, both in mining and in Alaska.

¹ For detailed table on Alaskan mineral production, see chapter of this volume on Statistical Summary of Mineral Production.

Whether, and if so when, this mine will be reopened means much in the future of the Territory. For well over half a century it has been true that any miner who was out of work and could make his way to Juneau could be sure of a job either in the Alaska Juneau or the Treadwell mines on Douglas Island across the channel, whose activities preceded those at Juneau. This was a fact of great social significance and also one that had an important effect in promoting the development of Alaska. Under wartime conditions and regulations it became impossible to operate the mine without continuous and increasing deficits, and so one of the great mines of the world was closed.

Many operations that were smaller and less famous but assured a living to resident Alaskans also closed. The big dredging enterprises managed to keep going, though on a very much reduced scale. The dredges themselves were not needed for war work, and the companies were not stripped of tools and equipment as completely as were smaller hand-operated properties, but even the dredge owners had their difficulties and losses. One of the first steps needed in restoration of the normal economy of the area will be a redistribution of picks and shovels, of caterpillars and bulldozers. Fortunately this has already begun. With completion of the defense construction projects these implements become surplus property and will be sold through the Reconstruction Finance Corporation. Local needs are to be given first consideration, and those who sold their equipment for Army use in time of need are to have priority in its repurchase. This should make possible a considerable resumption of mining in 1945.

Not all the mining industries in Alaska suffered as a result of the war. The Army needed fuel as well as men and equipment, so coal mining more than doubled its prewar output, yielding 352,000 short tons valued at \$2,369,000. Coal constituted the largest single element in Alaska's mineral production for the year. Although coal crops out widely over Alaska, significant coal mining has developed in only two fields—the Healy River in central Alaska and the Matanuska near Anchorage. Alaskan coals were formed in the Tertiary period and are characteristically high-volatile, low-heat-value fuels. In a few localities they have been altered incident to changes in the beds with which they are associated, becoming much better in quality and higher in value. In fact, coal of all grades, even the highest, is present and in places can be mined. Unfortunately the very processes that have improved the quality of the coal—the folding, bending, and breaking of the rocks incident to the operation of mountain-making forces or to intrusion of the sedimentaries by igneous rocks—have made it more difficult to mine the coal. The high-grade coals of Alaska, as in the Bering River and Matanuska fields, are folded, twisted, faulted, and so dislocated as to make mining difficult and expensive. To a considerable degree these difficulties become less troublesome as work on an individual property permits better understanding of the local structure, but nonetheless this condition constitutes a real handicap and adds permanently to the cost of mine development and operation.

When the war came the only operating coal mines were in the Healy River and Matanuska districts. All the other fields were marked by abandoned workings; and even the railroads, where extensions had been made to the mines, had been torn up. The Healy River field is capable of yielding great quantities of cheaply mined coal from thick beds cropping out near the Alaska Railroad, with which the mines are

collected by a spur. Unfortunately the coal is subbituminous and not of high grade, averaging but little over 9,000 B. t. u. It gets on the easily but is well-adapted to steam making and household heating, the principal uses in the interior.

In the Matanuska field two mines had survived among the numerous early mining ventures. One was the Eska, opened originally to supply fuel to the Alaska Railroad and owned by it. For some years the Eska mine had been closed, and in order to encourage private industry the railroad purchased its coal on contract, the Evan Jones mine being the principal producer. To meet the war demand the Eska mine was reopened so that the entire Evan Jones output would be available for Army and civilian use. An additional small mine was opened, but the fact that only a short-term demand could be foreseen prevented any large development. The market situation has prevented growth of coal mining in Alaska. The small population and the limited degree of local industrialization affords only a small domestic market. There has proved to be little opportunity to export coal, primarily because of the competition of petroleum. Indeed the latter is encroaching on the field for coal in Alaska itself.

Petroleum development in Alaska has been at a standstill now for some years. Far too little actual drilling has yet been done to prove or disprove the value of the several promising structures along the southern coast. Although seepages and other indications are known at a number of places, the drilling so far has indicated that any producing horizons of commercial importance, if present at all, will probably be at considerable depths. In the presence of other promising prospects requiring less money to explore, the major producing companies have not felt any strong urge to seek oil in Alaska. It may be present and in considerable quantities, but only the drill can tell. On the Arctic slope some progress is being made. A restudy of Naval Petroleum Reserve No. 4 led to the discovery of additional seeps and structures that seem to show promise. Drilling equipment was

Total value of mineral production of Alaska, 1880-1944¹

¹Source of figures, as follows—1880-1910: Bulletins on Mineral Industry of Alaska, prepared and issued by Alaskan Branch of Geological Survey; 1911-44: Mineral Resources of the United States and Minerals Yearbook, prepared and issued by Geological Survey (1911-23) and Bureau of Mines (1924-44).

sent up there in 1944 and in part was moved inland in the winter of 1944-45. It is expected that drilling will be begun on the Colville River dome in 1945. Development of global aviation and emphasis on the shorter northern routes have given new significance to possible petroleum fields of the Arctic coast.

METAL PRODUCTION

The following tables show the mine production of gold, silver, copper, and lead in Alaska in 1940-44 and 1880-1944, in terms of recovered metals; the output of gold and silver in 1944, by types of operation; and the output of gold, silver, copper, and lead from amalgamation and cyanidation mills (with or without concentration equipment) in 1944, by regions.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$40.711+	\$0.113	\$0.050	\$0.063

Kodiak Peninsula	53	15			
Kuskokwim	2,969	251		45,976	6,666
Seward Peninsula	15,207	1,841			

The mining region showing the largest production of gold in 1944 was the Seward Peninsula, followed in order of greatest output by the Yukon River Basin, Southeastern Alaska, Cook Inlet, Kuskokwim Kenai Peninsula, Copper River, and Northwestern Alaska regions. The Southeastern Alaska region was the largest producer of silver.

The largest producing lode mine and the largest individual producer of gold and silver in the Territory in 1944 was the Alaska Juneau Gold Mining Co. mine at Juneau. This property, operating at a greatly reduced capacity, was shut down indefinitely on April 9, 1944, as the result of a manpower shortage and a War Labor Board decision to award a 14-cent wage increase to all company employees. The company mined 378,800 tons of ore during its 1944 operations and produced 9,712 ounces of gold, 8,454 ounces of silver, and 4,000 pounds of copper. The Cleary Hill Mines Co. operated its mine on Cleary Creek in the Fairbanks district under a lode-mine permit from the War Production Board and shipped bullion to the Seattle Assay Office. About 20 men were employed in the operation. The Alaska Pacific Consolidated Mining Co. mine in the Willow Creek district north of Wasilla, idle since August 8, 1943, was permitted to resume operations in May. The 1944 operation was limited to repair and development.

Placer mines produced about 68 percent of the production of gold and 31 percent of the silver from Alaska in 1944. There were 9 floating connected-bucket dredges in operation in the Territory in 1944, compared with 7 in operation in 1943. The United States Smelting, Refining & Mining Co., largest producer of gold in Alaska before the present conflict, obtained a permit from the War Production Board to operate two of its dredges at Fairbanks and one at Nome. About 30 men were employed at Fairbanks in thawing, sluicing, stripping, and dredging operations, and bullion was shipped to the Government assay office in Seattle (Wash.). The Nome dredge was put in condition for an early start in 1945. The Arctic Circle Exploration Co. employed about 50 men in its dredging operation at Candle in the Seward Peninsula region. Other large dredging operations in Alaska in 1944 were the North American Dredging Co. at Flat and the New York Alaska Gold Dredging Co. at Nyac. In addition, about 189 mines were being worked by other types of placer operation in 1944.

In all, the War Production Board has issued operating permits to about 70 placer-mining operators, the largest being the United States Smelting, Refining & Mining Co., the Arctic Circle Exploration Co., Livengood Placers, Inc., New York Alaska Gold Dredging Co., Inland Dredging Co., and Wallace Porter. Permits also have been issued to 8 or 10 lode-mine operators, including the Cleary Hill Mines Co., Alaska Pacific Consolidated Mining Co., and the Alaska Empire Gold Mining Co. The employment of about 775 men so far has been authorized by the Board. Other small mines did not require a license to operate.

Copper.—Copper production in 1944 came from Southeastern Alaska and totaled 4,000 pounds valued at \$540, compared with 54,000 pounds valued at \$7,020 in 1943—a decline of 93 percent in quantity. The average weighted yearly price per pound for copper,

including bonus payments by the Metals Reserve Company for overquota production, advanced from \$0.130 in 1943 to \$0.135 in 1944.

Lead.—The lead production in Alaska in 1944 also came from the Southeastern region, where it was produced by the Alaska Juneau so long as that mine operated. Total output was 88,000 pounds valued at \$7,040, compared with 400,000 pounds valued at \$30,000 in 1943—a decline of 78 percent in quantity. The yearly weighted price of lead advanced from \$0.075 in 1943 to \$0.080 in 1944, which includes bonus payments by the Metals Reserve Company for overquota production. Lead ore occurs at a number of places in the Territory, but difficulties of transportation have so far prevented its being mined.

Platinum metals.—As heretofore, production of platinum in 1944 came mainly from the floating dredge and dragline operations of the Goodnews Bay Mining Co. on Salmon River in the Goodnews Bay district. Output was at a rate somewhat higher than in 1943. A small quantity of gold was recovered as a byproduct.

Mercury.—Contrary to the record for the States, production of mercury in Alaska in 1944 showed some gain. This was due to continuation of purchases by the Metals Reserve Company beyond January, at which time purchases closed in the States. Virtually all the 1944 output was made in the first half of the year, and no mine was active at the year end. The New Idria Alaska Quicksilver Mining Co. operated the Red Devil mine at Sleitmut through the winter of 1943-44, but operations ceased in June 1944. The Decoursey Mountain Quicksilver Mining Co. operated its mine and retort on Decoursey Mountain until June and shipped mercury to the Metals Reserve Company stock pile.

Tin.—In 1944, for the first time in many years, no tin ore seems to have been produced in Alaska although a small amount was received—presumably the result of earlier operations. The principal producer shut down in 1942, and with the virtual stoppage of gold placer mining, from which a small amount of tin concentrate was recovered as a byproduct, tin production ceased for the present.

Chromite.—The Chrome Queen Mining Co., only chromite producer in Alaska in 1944, resumed operations in the Kenai Peninsula region and shipped several lots of chromite to the Metals Reserve Company ore-purchasing depot at Jakolof Bay. Having completed the contract, the company closed the mine in August for an indefinite period.

Tungsten.—The J. H. Scott Co., operating in the Hyder district, made a small shipment, as did the Stepovich mine near Fairbanks. Some of the Stepovich ore yields a 60-percent WO_3 product, and there are various prospects that offer possibility of becoming producers.

Antimony.—The Stampede mine in the Kantishna district was idle in 1944, and the only producer was Ernest Maurer on Slate Creek, who shipped 73 tons of 48-percent ore.

Other metals.—No production of iron ore, manganese, molybdenum, or vanadium was recorded from Alaska in 1944. Diamond drilling on the Kasaan Peninsula in the winter of 1943-44 revealed over 1,000,000 tons of iron-copper ore. Results obtained to date are encouraging, and indications are that further exploration will yield favorable results. Drilling in Southeastern Alaska revealed the presence of considerable tonnages of nickel-copper ores, but the grade was low.

NONMETALLIC PRODUCTION

In 1944, for the first time in the history of Alaskan mining, the value of the yield of nonmetals exceeded that of the metals, amounting to \$3,700,000 as compared with \$3,300,000 for the metals. The two totaled but \$7,000,000, compared with a prewar total of \$28,724,000 as in 1940. The reasons for this great decline have already been discussed.

Coal.—Coal output in 1944 totaled 352,000 tons valued at \$2,369,000 as compared with 289,232 tons and \$1,842,708 in 1943. There are reasons for believing that this production exceeded consumption for the year and that some 30,000 tons went into stock piles. It seems probable that the output in 1945 will be less than in 1944, as the active construction projects of the Army and Navy have largely been completed, and that hereafter only the fuel needed for operation of the new bases will be called for. As already indicated, the recorded output came only from the Matanuska and Healy River fields. Small quantities probably were dug out for strictly local use elsewhere, but at present the only significant mining is in these two districts. A new small mine, the Buffalo, came into operation in the Matanuska field.

Sand and gravel.—Based on reports from the Alaska Road Commission, National Park Service, Public Roads Administration, and the Army and Navy, it is estimated that in 1944 the output amounted to 712,496 short tons valued at \$499,269.

Stone.—Production of crushed stone in Alaska in 1944 was considerable, but figures can not be released at this time.

Asbestos.—A deposit of tremolite asbestos has been developed in the Dahl Creek area, Kobuk River district, and small shipments were made in 1944. The material is of good quality. An important use is for making chemical filters.

An unusual occurrence of asbestos appears on Lemesurier Island, Southeastern Alaska. Lenses 6 to 8 inches wide of "mountain leather," consisting of matted fibers resembling buckskin, occur in bed seams and cross joints in limestone. It has been identified as paligorskite, an amphibole asbestos. Mountain leather has appeared heretofore chiefly as museum specimens. As this Alaskan occurrence may afford a small tonnage it may be possible to put it to commercial use.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN ARIZONA

(MINE REPORT)

By G. E. WOODWARD AND PAUL LUFF

SUMMARY OUTLINE

	Page		Page

SUMMARY

Despite a decrease of 7 percent from \$121,212,902 in 1943 to \$113,094,806 in 1944 (see fig. 1), the total value of gold, silver, copper, lead, and zinc in terms of recoverable metals from Arizona mines exceeded that for the same five metals produced in 1944 in any other State. In both quantity and value the output of gold, silver, and copper decreased substantially, but the quantity and value of lead and zinc increased. The total value of the gold was \$3,925,670—a 33-percent loss from 1943; silver, \$3,124,650—a 23-percent loss; and copper, \$96,741,810—an 8-percent loss. The value of the lead was \$2,673,120—a 30-percent gain; and zinc, \$6,629,556—a 56-percent gain. The value of the gold production represented 3 percent of the State total value, silver 3 percent, copper 86 percent, lead 2 percent, and zinc 6 percent. The value of the metals recovered from copper ore was \$101,163,271 in 1944 (\$112,020,217 in 1943), or 89 percent of the State total. The output of lead in 1944 was the largest in any year in the history of the State, and the production of zinc exceeded the record output of 1943.

Production of gold, silver, copper, lead, and zinc in Arizona in 1944 was affected by several factors: A serious shortage of labor, which was the primary cause of a loss in output of gold, silver, and copper; the completion in January of the work of increasing the capacity (from 25,000 to 45,000 tons of ore a day) of the copper concentrator and smelter at the Morenci property of the Phelps Dodge Corporation; the large output of zinc-lead ore from the Copper Queen property at Bisbee and the San Xavier mine near Sahuarita; the loss of about 4,000,000 pounds of copper a month during the last quarter of the year from the Inspiration property at Inspiration, caused by a fire on October 1 which destroyed the electrolytic tank house; the fire on Labor Day which destroyed the shaft, gallows frame, ore bins, and other structures at the zinc-lead property of the Mammoth-St. Anthony Limited at Tiger; the suspension of operations in July at the Duquesne zinc-lead-copper mine near Patagonia by the Callahan Zinc-Lead Co.; and the closing in October of the zinc-lead property of the Tennessee-Schuylkill Corporation at Chloride.

The effect of the labor shortage on the domestic copper industry was especially acute owing to the fact that Arizona has seven large

copper-producing districts and six copper smelters. Copper production in Arizona reached the highest rate (about 72,800,000 pounds a month) in March and dropped to the lowest rate (about 46,800,000 pounds) in November.

Since the inauguration in February 1942 of the Government premium price plan, the base price of copper, lead, and zinc has remained unchanged; copper has been \$0.12 a pound, lead \$0.065 a pound (New York), and zinc \$0.0825 a pound. The basic Government policy of premium payments for overquota production remained in force throughout 1944.

Considerable assistance was given to mine operators in Arizona in 1944 by the Grazing Service of the United States Department of the Interior, which built access roads to various properties. About 48 applications for roads were investigated, of which 20 were approved and 28 disapproved; the estimated cost of building the approved roads was \$138,700. Most of the roads approved for construction were to copper, zinc-lead, and zinc-copper properties. Some access roads also were constructed by the Indian Service and the Forest Service. The Federal Bureau of Mines, in cooperation with the Federal Geological Survey, did considerable work in 1944 exploring and testing various properties throughout the State. Most of this work was drilling test holes at the San Manuel copper deposit near Tiger in Pinal County, the Apache iron deposit near Cibecue in Navajo County, the Amargosa molybdenum deposit near Sahuarita in Pima County, the Bullard copper mine near Aguila in Yavapai County, and the Christmas copper mine near Winkelman in Gila County. Assistance was given to the small mine operators in Arizona by the Department of Mineral Resources (State of Arizona), and the Reconstruction Finance Corporation made numerous mine development (class B) loans and accessibility (class C) loans to Arizona operators in 1944.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063
1941.....	35.00	¢.711+	.118	.057	.075

¹ Includes placer sands treated by dry concentration plants.

² A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

Gold.—The output of recoverable gold in Arizona in 1944 was 112,162 fine ounces—a 35-percent decrease from 1943. Gold from siliceous ores (chiefly dry and siliceous gold ore) declined 15,093 ounces or more than 58 percent, that from copper ore 32 percent, and that from zinc-lead ore nearly 25 percent. Gold from placers declined from 319 to 242 ounces. The Copper Queen (Bisbee) branch of the Phelps Dodge Corporation continued to be the leading gold producer in Arizona, although its output declined 35 percent from that in 1943;

FIGURE 1.—Value of mine production of gold, silver, and copper and total value of gold, silver, copper, lead, and zinc in Arizona, 1870-1944. The value of lead and zinc has been less than \$2,000,000 annually, except in a few years.

it was followed by the New Cornelia mine in Pima County, the United Verde mine in Yavapai County, the Magma mine and the Mammoth-St. Anthony Limited property (both in Pinal County), the Morenci branch of the Phelps Dodge Corporation in Greenlee County, and the Iron King mine in Yavapai County; these seven properties produced 84 percent of the State total gold. Copper ore yielded 81 percent of the State total gold, siliceous ores nearly 10 percent, zinc-lead ore more than 6 percent, and lead ore and zinc-copper ore nearly all the remainder. The chief gold-producing districts in Arizona were the

Warren (38,401 ounces), Ajo (29,020), Verde (8,620), Pioneer (Superior) (6,630), Old Hat (6,389), Big Bug (5,409), and Copper Mountain (Morenci) (5,389 ounces).

Silver.—The output of recoverable silver in Arizona in 1944 was 4,394,039 fine ounces—a 23-percent decrease from 1943. The chief decreases were 1,260,601 ounces in silver from copper ore, 193,711 ounces from siliceous ores, and 24,753 ounces from zinc-lead-copper ore; however, the output of silver from zinc-lead ore increased 151,170 ounces. Copper ore yielded 71 percent of the State total silver, zinc-lead ore 18 percent, siliceous ores 4 percent, zinc-copper ore nearly 4 percent, lead ore 2 percent, and zinc-lead-copper ore 1 percent. The Phelps Dodge Corporation continued to be the chief silver producer in Arizona, although its output was nearly 32 percent less than in 1943; its four properties (Copper Queen, Morenci, New Cornelia, and United Verde) produced 68 percent of the State gold output, nearly 59 percent of the silver, and 58 percent of the copper. Other large silver producers in Arizona in 1944 were the Magma, Iron King, Trench-Flux, San Xavier (Eagle-Picher Mining & Smelting Co.), Shattuck Denn, and Castle Dome properties. The chief silver-producing districts were the Warren (1,550,506 ounces), Verde (589,538), Pioneer (Superior) (386,429), Ajo (319,320), Copper Mountain (Morenci) (281,153), Big Bug (229,490), Globe-Miami (187,612), Harshaw (176,438), and Pima (149,265 ounces); nearly 49 percent of the State total silver came from the Warren and Verde districts, but the output from these districts decreased 1,148,400 ounces from 1943.

Copper.—Arizona has been the outstanding producer of copper in the United States since 1907 except in 1909, when Montana held first place. The output of recoverable copper in Arizona in 1944 was 716,606,000 pounds—an 11-percent decrease from 1943. The Copper Mountain (Morenci) district, with an output of 213,851,000 net pounds of copper, was the leading copper-producing area in the State; it was followed by the Globe-Miami district with 190,609,200 pounds, Ajo with 92,500,000, Warren (Bisbee) with 65,366,000, Mineral Creek (Ray) with 54,904,200, Verde (Jerome) with 52,429,000, and Pioneer (Superior) with 25,444,800 pounds. Marked decreases in copper output were recorded in each of these districts except the Copper Mountain (Morenci), where the output increased 45,156,600 pounds; these seven districts contributed 97 percent of the State total copper. Copper ore and its products yielded 709,366,574 pounds of copper, as follows: 31,069,798 tons of copper ore treated by concentration yielded 75 percent; 1,087,707 tons of copper ore shipped crude to smelters, 14 percent; and 3,131,360 tons of copper ore leached and 14,814 tons of cement copper (from mine-water precipitates and underground leaching operations), 11 percent. The Morenci branch of the Phelps Dodge Corporation was again the largest copper producer in Arizona in 1944; it was followed in order by the New Cornelia branch of the Phelps Dodge Corporation, Inspiration, Copper Queen, Miami, Ray (Kennecott Copper Corporation), United Verde, Castle Dome, Magma, and Bagdad properties.

Lead and zinc.—The output of recoverable lead in Arizona in 1944 was 33,414,000 pounds—the largest in any year in the history of the State and 22 percent more than in 1943. The output of recoverable zinc was 58,154,000 pounds—a 48-percent increase over the record output of 1943. The full calendar year operations at the zinc-lead

ore body of the Copper Queen mine at Bisbee and the San Xavier mine near Sahuarita accounted for most of the State increase in lead and zinc output; such operations at the Copper Queen mine were begun in November 1943 and at the San Xavier mine in September 1943. About 21 percent of the State total lead and 28 percent of the zinc came from mines at Bisbee in Cochise County, 26 percent of the lead and 22 percent of the zinc from Pinal County, nearly 15 percent of the lead and 18 percent of the zinc from mines near Sahuarita in Pima County, and 15 percent of the lead and 11 percent of the zinc from mines near Patagonia in Santa Cruz County; most of the remaining lead and zinc output came from Yavapai, Mohave, and Gila Counties. About 83 percent of the total lead and 80 percent of the total zinc came from zinc-lead ore; nearly all the rest of the lead came from lead ore, siliceous ores, zinc-lead-copper ore, zinc-copper ore, and zinc ore; and all the rest of the zinc came from zinc-copper ore, zinc-lead-copper ore, and zinc ore. The Mammoth-St. Anthony Limited property at Tiger was the leading producer of lead in the State in 1944; it was followed in order by the Copper Queen mine at Bisbee, San Xavier mine near Sahuarita, Trench-Flux group near Patagonia, Iron King mine at Humboldt, Tennessee mine at Chloride, and Arizona Lead Co. property near Yuma. The principal producer of zinc in the State in 1944 was the Copper Queen mine at Bisbee; it was followed in order by the San Xavier, Magma, Iron King, Mammoth-St. Anthony Limited, Trench-Flux, Duquesne, and Tennessee properties.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Arizona in 1944, by counties, in terms of recovered metals

MINING INDUSTRY

The mining of copper ore, by far the most important part of the mining industry in Arizona, was seriously handicapped in 1944 by a shortage of labor, which became so acute by fall that some of the large producers of copper ore had to curtail the mining of ore 40 percent. The total production of ore of all classes dropped from the record of 36,630,788 tons in 1943 to 35,900,641 tons in 1944. The output of copper ore was 35,288,865 tons—a 2-percent loss from 1943; zinc-lead ore, 337,940 tons—a 29-percent gain; zinc-copper, 96,603 tons—a 9-percent gain; lead ore, 27,101 tons—a 34-percent loss; and zinc-lead-copper, 18,578 tons—a 31-percent loss. The output of siliceous ores was 129,086 tons compared with 186,185 tons in 1943—a 31-percent decline. Of the State total ore, 35,147,844 tons (98 percent) was copper ore mined in the Globe-Miami, Copper Mountain (Moenkopi), Ajo, Mineral Creek (Ray), Warren (Bisbee), Eureka (Hillside), Verde (Jerome), and Pioneer (Superior) districts; 97 percent of the State total zinc-lead ore was mined in the Big Bug, Warren (Bisbee), Yuma, Harshaw, Old Hat (Oracle), and Wallapai (Chloride) districts; all the zinc-lead-copper ore came from two properties—one in the

Patagonia district and the other in the Big Bug district; 92 percent of the zinc-copper ore came from one mine in the Pioneer (Superior) district; nearly 61 percent of the lead ore from one property in the Castle Dome district; and 58 percent of the zinc ore from one mine in the Pima district. More than 78 percent of the State total gold ore came from three properties—in the Old Hat (Oracle), Owens, and Bullard districts; 76 percent of the gold-silver ore from one property in the Copper Mountain (Morenci) district; and 70 percent of the silver ore from one mine in the Ash Peak district. Mining operations at two open pits—Ajo and Morenci—produced a total of 17,722,944 tons of copper ore.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Arizona in 1944, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

Total, 1943.....	293	36,630,788	171,810	5,713,889	806,362,000	27,454,000	39,354,000

¹ Includes 295 ounces recovered from underground mine-water precipitates.

² Includes 79,003,481 pounds recovered from ore leached and mine-water precipitates.

³ A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

⁴ Includes 117,416,341 pounds recovered from ore leached and mine-water precipitates.

METALLURGIC INDUSTRY

Of the 35,900,641 tons of ore produced in 1944 in Arizona, 31,543,180 tons (88 percent) were treated at concentration plants; 3,131,360 tons (9 percent) at a leaching plant; 30,443 tons (less than 0.1 percent) at cyanidation and cyanidation-concentration mills; and 1,195,658 tons (3 percent) were shipped crude to smelters. No ore was treated at amalgamation mills in Arizona in 1944, but 30,443 tons of siliceous material were treated (144,338 tons in 1943) at cyanidation and cyanidation-concentration plants; 2,950 tons of material were treated at two straight cyanidation plants in 1944 compared with 24,700 tons at four plants in 1943; the most important of these plants was that at the Mammoth-St. Anthony Limited property at Tiger, and this plant closed July 31.

Ore treated at concentration plants in 1944 comprised chiefly 31,069,798 tons of copper ore, 337,684 tons of zinc-lead ore, 96,603 tons of zinc-copper ore, 18,578 tons of zinc-lead-copper ore, and 16,634 tons of lead ore. Copper ore from the Miami property was treated by

a combination of leaching and concentration, and copper ore from the Inspiration mine was treated by straight leaching and by leaching and concentration. The large copper-concentration plants at Ajo (25,000-ton-a-day), Clarkdale (2,100-ton), Hayden (10,000-ton), Miami (18,000-ton), Inspiration (18,000-ton), and Superior (850-ton) were operated continuously in 1944 but at a much lower rate than in 1943, whereas those at Morenci (45,000-ton), Castle Dome (10,000-ton), and Hillside (Bagdad) (2,500-ton) were operated at a higher rate than in 1943. The copper-leaching plants at Inspiration (9,000-ton) and Miami (3,000-ton) and the copper smelters at Clarkdale, Douglas, Hayden, Miami, Morenci, and Superior were operated also at a reduced rate with the exception of the smelter at Miami. The rated capacity of charge of the six copper smelters was as follows: Clarkdale, 1,400,000 tons per year; Douglas, 1,600,000; Hayden, 360,000; Miami, 360,000; Morenci, 600,000; and Superior (Magma), 210,000 tons. The Phelps Dodge Corporation reported that the Douglas smelter operated throughout the year and smelted a total of 925,431 tons (1,162,830 tons in 1943) of new material. Furnace operations varied between a straight calcine charge and a mixed calcine and raw charge. Extensive furnace repairs and a shortage of receipts late in the year prevented utilization of the maximum furnace capacity. The smelter at Clarkdale treated 518,627 tons of new material in 1944 compared with 875,953 tons in 1943. After the first 2 months of the year smelting operations were confined to one reverberatory furnace and two converters. The Morenci smelter treated 422,320 tons of new material in 1944 compared with 443,373 tons in 1943; operating conditions remained difficult throughout the year, and metallurgy was handicapped. Labor shortages prevented full utilization of smelting facilities, and surplus concentrates were shipped to the Douglas smelter. The 20-ton smelter at Tiger is the only lead smelter in Arizona; it operated exclusively on concentrates from the mill of Mammoth-St Anthony Limited until July 31, when operations ceased. Nearly all the lead concentrates produced at mills in Arizona in 1944 were shipped to the smelter at El Paso, Tex., and all the zinc concentrates were shipped to smelters at Amarillo, Dumas, and Corpus Christi, Tex., and Bartlesville and Henryetta, Okla.

The following tables give details of the treatment of all ores produced in Arizona in 1944.

Mine production of metals in Arizona in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Old tailings, and current						
tailings cyanided	29,561	656	1,767			
Concentrates smelted	1,216,175	60,710	2,372,667	537,638,149	30,290,131	57,755,263
Smelted	1,195,658	50,554	2,019,220	99,964,370	3,123,869	398,737
Slurry precipitates smelted	14,814		295	121,211,424		
Slurry ore leached	3,131,360		57,792,057			
Slurry		242	90			
		112,162	4,394,039	716,606,000	33,414,000	58,154,000
Total, 1944		171,810	5,713,889	806,362,000	27,454,000	39,354,000

Distribution as follows: Cochise County, 600,000 pounds; Gila County, 9,252,711 pounds; Greenlee County, 2,414,400 pounds; Pinal County, 8,380,913 pounds; and Yavapai County, 563,400 pounds.

Treated by straight leaching at 1 plant in Gila County.

Mine production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Arizona in 1944, by types of mills and by counties, in terms of recovered metals

1 Ellsworth district lies in both Maricopa and Yuma Counties.

2 White Picacho district lies in both Maricopa and Yavapai Counties.

3 Old Hat district lies in both Pima and Pinal Counties.

COCHISE COUNTY

California district (Hilltop).—The Crosby mine near Portal was the only producer in the California district in 1944; a lessee operated the mine nearly all the year and shipped 1,011 tons of copper ore to a smelter.

Cochise district.—William A. Hooton operated the Mammoth mine 7 miles north of Dragoon in 1944 and shipped 1,543 tons of copper ore to smelters in Arizona and 2,160 tons of zinc-copper ore to the custom flotation mill of the Eagle-Picher Mining & Smelting Co. near Sahuarita; the rest of the district output was 648 tons of low-grade copper ore produced from the Centurion mine by the Captain Copper Co. The Coronado Copper & Zinc Co. developed its ore body at the Republic mine throughout the year and started erecting a 150-ton flotation mill.

Dos Cabezas and Tevis district.—All the output (373 tons) of the Dos Cabezas and Tevis district in 1944 was highly siliceous copper ore produced from the Tout group.

Golden Rule (Dragoon) district.—A lessee operated the Dragoon Zinc mine a short time in 1944 and shipped 256 tons of zinc ore to the Shattuck Denn custom flotation mill at Bisbee.

Hartford (Huachuca Mountains) district.—The State of Texas mine near Hereford was operated throughout 1944, and 191 tons of zinc-lead ore were shipped to a custom flotation mill at Bisbee; the rest (50 tons) of the district output was virtually all silver-lead ore produced from the Armistice property.

Swisshelm district (Elfrida).—Leasing operations at the Scribner mine from May 1944 to the end of the year produced 1,232 tons of silver-lead ore, which was shipped direct to the smelter at El Paso, Tex.

Tombstone district.—Mining operations in the Tombstone district have declined greatly during the past decade. In 1944 the output of ore dropped to 1,265 tons, and it was virtually all silver-lead ore shipped to a smelter from the Tombstone Extension mine.

Turquoise district (Courtland, Pearce, Gleeson).—In 1944 a total of 1,502 tons of smelting ore was produced from four mines in the Turquoise district—997 tons of copper ore from the Shannon group, 170 tons of silver-lead ore and 55 tons of copper ore from the Tom Scott mine, 199 tons of silver-copper ore from the Black Diamond mine, and 48 tons of lead ore and 33 tons of zinc ore from the Defiance property.

Warren district (Bisbee, Warren).—In 1944 the Warren district ranked first in the State in output of gold, silver, and zinc, second in lead, and fourth in copper; however, the output of gold, silver, and copper was much less than in 1943 and the production of lead and zinc much greater. The principal output was copper ore and zinc-lead ore from the Copper Queen branch of the Phelps Dodge Corporation. The company reported that 634,650 tons of copper ore were shipped direct to the smelters at Douglas and Clarkdale; these shipments included 3,998 tons of low-grade marginal ore mined for the account of Metals Reserve Company and sent to Clarkdale for treatment (shipments of this class of ore ceased in January) and 157,148 tons of siliceous flux ore produced from the "Southeast Extension" porphyry ore body for the Douglas smelter. In addition,

733 tons of copper precipitates were produced by the surface and underground precipitation plants, and 55,571 tons of zinc-lead ore were shipped to custom flotation mills near Bisbee and Sahuarita.

According to the company annual report for 1944, efforts to achieve maximum copper production in 1944 were seriously handicapped by a shortage of manpower, resulting in a marked decline in the output of copper, gold, and silver. The contract with Metals Reserve Company made in April 1943, for the shipments of copper ore from the "Cole Division" to the Clarkdale smelter, was modified to include higher-grade copper ore from the "Junction Division," but this contract was terminated in September 1944 by the Metals Reserve Company. A total of 31,817 feet of exploration and development headings was driven in 1944, as well as 5,318 feet of stope preparation and 28,054 feet of diamond drilling. In the face of operating difficulties that existed throughout the year it is considered that ore reserves were satisfactorily maintained. No new copper ore bodies of any extent were developed, but the zinc-lead ore exploration was encouraging.

Mining and milling operations at the Denn property of the Shattuck Denn Mining Corporation were continuous throughout the year; 66,688 tons of copper ore were shipped to the smelter at El Paso, Tex., and 3,440 tons of zinc-lead ore were treated by flotation. The company 150-ton flotation mill was utilized in 1944 principally for the treatment of custom ores, which totaled 50,246 tons. Nearly 82 percent of this ore was zinc-lead ore from the Copper Queen mine at Bisbee. The rest of the district output was 5,024 tons of copper ore shipped by a lessee working the Shattuck mine.

COCONINO COUNTY

Jacob Canyon and Warm Springs district.—The Mackin-Kennedy-Ryan group and the Petoskey group were leased in April 1944 by Atherley & Ryan. During the year 10,826 tons of carbonate copper ore were mined by a power shovel from surface pits at both groups and shipped to the smelter at Garfield, Utah. The remainder of the district output was a small lot (4 tons) of similar ore from the Brown Derby claim.

Kaibito Plateau district.—About 2,000 tons of highly siliceous copper ore were mined and shipped in 1944 from the Mardun property 57 miles north of Cameron. The Mardun Co. operated the property throughout the year and completed a 120-ton concentration plant

GILA COUNTY

Banner and Dripping Springs district.—A total of 26,227 tons of ore was produced in the Banner and Dripping Springs district in 1944; the principal output was 21,988 tons of copper ore shipped direct to a smelter from the Christmas mine by Sam Knight Mining Lease, Inc. The rest of the district output was mainly zinc-lead ore (4,109 tons) produced from the "79" mine by the 79 Lead-Copper Co. and treated in the Shattuck Denn custom mill at Bisbee. The Shattuck Denn Mining Corporation owns an approximate 60 percent interest in this mine; according to its annual report for 1944, the 79 Lead-Copper Co. was engaged in developing a new ore body that was encountered during the year. Shipments of zinc-lead ore from this new ore body and from an older ore body enabled the 79 Lead-Copper Co. to improve its financial condition materially.

Globe-Miami district.—The Globe-Miami district, with a production of 190,609,200 net pounds of copper in 1944 (201,026,600 net pounds in 1943), dropped from first place in 1943 to second in 1944 among the important copper-producing areas in Arizona; the Copper Mountain (Morenci) district in Greenlee County took first place. The Inspiration property, with a yield of 81,996,557 net pounds of copper (110,259,203 net pounds in 1943), was again the chief producer of copper in the district and ranked third in the State. The principal causes of a decreased production of copper were the shortage of labor throughout the year and the destruction by fire October 1 of the electrolytic tank house. The Inspiration Consolidated Copper Co. reported that 3,131,360 tons of ore from which the slimes had been removed were treated in the main leaching plant. This ore averaged 1.154 percent copper—0.589 percent copper as oxide and 0.565 percent as sulfide. Ferric sulfate leaching was used to treat 2,525,856 tons of ore during the first 9 months of the year, and during the last 3 months 605,504 tons of ore were treated with sulfuric acid solution. Extraction during the ferric sulfate leaching period was 98.38 percent of the oxide and 76.25 percent of the sulfide, or 88.26 percent of the total copper. The slimes (203,734 tons averaging 1.491 percent copper) removed from the ore were treated at the concentrator and the tailings from this operation were treated by sulfuric acid leaching, resulting in a combined recovery from concentration and leaching of slimes of 82.83 percent of the total copper. Leach-float operations on crude copper ore were carried on from the beginning of the year until August 3, when insufficient mine labor to produce the required tonnage of ore necessitated a suspension of such operations. During this period the leach-float plant treated 627,617 tons of ore averaging 1.174 percent copper—0.419 percent as oxide and 0.755 percent as sulfide; extraction was 85.83 percent of the total copper. From August 4 to September 20 the leach-float plant was used for testing a mixture of crude copper ore and slimes and on slimes alone; a total of 54,073 tons of material was treated during this testing period. During the last 3 months of the year 528,350 tons of leaching-plant tailings averaging 0.735 percent copper were treated at the concentrator; extraction was 77.46 percent of the total copper. In addition, 67 tons of leaching-plant cleanings and 109 tons of mine-water precipitates were shipped direct to the International smelter at Miami.

According to the annual report of the company for 1944, ore mined during the year totaled 4,016,784 dry tons assaying 1.175 percent copper—0.586 percent as oxide and 0.589 percent as sulfide. Total underground development aggregated 47,837 feet of drifts and raises and 4,821 cubic yards of miscellaneous development. After the electrolytic tank house was destroyed by fire October 1, as continuity of operations was urgently requested by representatives of the War Production Board the "Dual Process" (combined leaching and concentration) was substituted for the ferric sulfate leaching process. This change was completed by October 15, and operations are continuing satisfactorily although at a lower production rate than before the fire. Reconstruction of the tank house is proceeding as rapidly as possible, but resumption of the use of the ferric sulfate leaching process is not expected earlier than May 1945.

Mining and milling at the Miami property of the Miami Copper Co. were continuous throughout the year. The company 18,000-ton

concentrator and 3,000-ton leaching plant treated 4,717,138 tons (5,273,828 tons in 1943) of ore averaging 0.653 percent copper, and 3,839 tons of copper precipitates were produced from leaching of ore in place. In addition, 562 tons of molybdenum concentrates were recovered as a byproduct in treating copper ore. The Castle Dome Copper Co., Inc., a wholly owned subsidiary of Miami Copper Co., operated its open-pit mine near Miami continuously and treated 4,107,975 tons of ore averaging 0.708 percent copper; the capacity of the flotation plant, owned by Defense Plant Corporation and leased to the Castle Dome Copper Co., Inc., was increased from 10,000 to over 12,000 tons of ore a day during the last quarter of the year. According to the annual report of the Miami Copper Co. for 1944, operations at the open pit of the Castle Dome property more than fulfilled expectations and produced 49,987,529 net pounds of copper. Although the production of copper from the Miami mine fell considerably because of critical labor shortages, the combined production (106,136,695 net pounds of copper) from the Miami and Castle Dome mines was the highest for any year in the history of the company. Mine development in 1944 at the Miami property comprised 8,505 feet of drifts and 7,606 feet of raises. In addition, 25,724 feet of drifts and raises were driven in preparation for stoping. Although every effort was made to operate the mine at capacity, the shortage of labor became more critical during the year and reduced the production to an average of 82 percent of capacity; during the last few months of the year the manpower situation had deteriorated to such an extent that the mine was operated on two shifts instead of three. In addition to the serious curtailment of copper production, mine development has necessarily been so reduced that production may be curtailed even further in the near future. Moreover, the reserve of broken ore on hand in the mine at the end of the year was reduced to only 51 percent of that at the beginning. Operations at the Castle Dome property began in June 1943, so that 1944 represents the first full calendar year in operation. The shortage of labor at this open-pit mine is not as critical as that at the underground Miami mine. However, the open-pit mine is experiencing a very critical shortage of 14- by 24-inch rubber tires for the ore trucks, resulting in curtailment of stripping operations to favor current ore output; if continued, this may adversely affect future ore production.

The rest of the district output was largely copper ore (23,829 tons) shipped direct to a smelter by lessees from various claims and waste dumps of the Old Dominion property; copper ore shipped also from the Carlota mine (9,310 tons), Al & Hal claims (4,780 tons), Superior & Boston mine (3,842 tons), and Van Dyke mine (3,377 tons); and a total of 718 tons of lead ore shipped from the Albert Lea, Defiance, Gem, and Silver Bell properties.

Pioneer (Pinal Mountains) district.—Lessees operated the Bobaway and Mariana claims of the Bob Tail group in 1944 and shipped a total of 99 tons of silver-copper ore to a smelter.

Summit district.—The only output in the Summit district in 1944 was 349 tons of copper ore shipped to a smelter from the Gibson waste dump.

GRAHAM COUNTY

Aravaipa district.—Mining was carried on throughout the year at the Aravaipa group by the Athletic Mining Co.; a total of 4,017 tons of zinc-lead ore was shipped to custom milling plants near Bisbee and Sahuarita. The company plans to erect a milling plant at its property in the near future. The rest of the district output was 100 tons of lead ore produced from the Last Chance mine.

Lone Star district.—The Horseshoe mine 12 miles northeast of Safford was operated a short time in 1944, and 182 tons of copper ore were shipped to the smelter at Miami.

GREENLEE COUNTY

Ash Peak district.—Approximately 8,058 tons of fluxing ore averaging 0.03 ounce of gold and 6.43 ounces of silver to the ton and 84.40 percent silica were mined in 1944 from the Ash Peak mine by Ash Peak Lease and shipped to the International smelter at Miami. Similar ore (352 tons) was shipped from the Golden Eagle (Hardy) mine.

Copper Mountain district (Morenci).—The Copper Mountain district, with a production of 213,851,000 net pounds of copper in 1944 (168,694,400 net pounds in 1943), was the chief copper-producing area in Arizona. The Morenci mine of the Phelps Dodge Corporation was the outstanding producer of copper in the State. The company reported that 11,265,526 tons of copper ore were treated in the combined (Phelps Dodge and Defense Plant Corporation) 45,000-ton concentrator and that 46,571 tons of crude copper ore, 1,913 tons of copper precipitates, and 3,347 tons of old Clifton smelter cleanings were shipped direct to the Morenci smelter.

According to the annual report of the Phelps Dodge Corporation for 1944, the Defense Plant Corporation facilities at Morenci, Ariz., and El Paso, Tex., which are rented to the Phelps Dodge Corporation, began operating early in 1944. However, deficiency in manpower, resulting in curtailed ore production, prevented the utilization of these facilities to full capacity. At the Morenci open pit 11,328,097 tons of ore and 19,909,488 tons of waste material were extracted. Operations were conducted on 16 mining benches, ranging from the 4,600- to the 5,350-foot level; work on the 4,600-foot bench was begun during the last month of the year. All the construction work connected with the Defense Plant Corporation expansion program was essentially completed during 1944 except for some work at the open pit.

Nearly all the rest of the district output was crude, high-silica, copper oxide ore (4,110 tons) from the Keating mine, operated under lease by the Auto Specialties Manufacturing Co.

MARICOPA COUNTY

New River (Moore's) district.—Mining of sulfide copper ore was carried on at the Orizaba mine from January through May 1944, and 2,670 tons of ore were shipped to the smelter at Hayden; after May the mine was allowed to fill with water.

Osborn district.—In 1944 three properties—the Belmont-McNeil, U. S. (Furlough), and Moon Anchor—in the Osborn district were operated by the East Vulture Mining Co. The output comprised 3,427 tons of gold-silver-copper-lead ore and 320 tons of gold ore from

the Belmont-McNeil mine, 2,598 tons of low-grade gold ore from the U. S. waste-dump, and 240 tons of gold ore and 147 tons of lead ore from the Moon Anchor mine. Some of the ore was treated in a flotation plant, but most of it was shipped crude to various smelters.

Vulture district.—Nearly all the mines in the Vulture district have been idle since the Government gold-mine closing order of October 1942. Virtually all the 2,711 tons produced in 1944 was old tailings (gold) from the Vulture dump treated by cyanidation.

Wickenburg district.—Lessees continued in 1944 to work an old tailings dump at Wickenburg; 1,364 tons of low-grade gold material were shipped to various smelters in Arizona and 252 tons of similar material were treated by concentration.

MOHAVE COUNTY

Cedar Valley district.—Leasing operations at the Antler mine 20 miles southeast of Yucca by the Arizona Antler Mining Co. produced 1,568 tons of ore in 1944; most of it was zinc-copper ore shipped to a custom flotation mill at Midvale, Utah. Similar ore (766 tons) was produced from the Copper World mine by lessees and also shipped to Midvale for treatment.

Hacks Canyon district.—The Canyon Copper Co. continued in 1944 to operate the Hacks Canyon mine south of Fredonia and shipped 86 tons of carbonate copper ore to a smelter in Utah.

Orems (McCracken and Potts Mountain) district.—Lessees operated the Cleopatra mine from January through May 1944 and shipped 8,578 tons of high-silica gold-copper ore to the smelter at Clarkdale. The rest of the district output was virtually all crude copper ore (690 tons) produced from the Cactus Queen and Stein properties.

Wallapai district (Cerbat, Chloride, Mineral Park, Stockton Hill).—Zinc-lead ore produced from the Tennessee mine at Chloride by the Tennessee-Schuylkill Corporation continued to be the most important output in the Wallapai district; however, the property was closed October 6, 1944, largely because of an insufficient supply of labor. In December the president of the company was attempting to make arrangements to resume operations. During the year 20,300 tons of zinc-lead ore were treated in the company 150-ton flotation plant, which yielded 1,160 tons of lead concentrates and 1,900 tons of zinc concentrates. The Emerald Isle Copper Co. worked its property throughout the year, shipped 8,625 tons of crude carbonate copper ore to the smelter at Clarkdale, and completed erecting a 300-ton leaching plant. Leasing operations at the Summit group from February through December produced 3,131 tons of zinc-lead ore, which was shipped to a custom flotation mill at Midvale, Utah. The remainder of the district output was mainly zinc-lead ore (1,156 tons) from the Juno, Eureka, Hidden Treasure, Latest Out, and Minnesota-Connor properties.

PIMA COUNTY

Ajo district.—The Ajo district, with a production of approximately 92,500,000 net pounds of copper in 1944, ranked third in copper output among the copper-producing areas in the State, and it ranked second in gold and fourth in silver output; all the output came from the New Cornelia mine of the Phelps Dodge Corporation. The open pit at the property and the 25,000-ton concentrator were operated continuously throughout the year; the concentrator treated 6,454,071 tons of copper

ore in 1944 compared with 8,956,698 tons in 1943. According to the annual report of the Phelps Dodge Corporation for 1944, the New Cornelia open pit produced 6,454,878 tons of copper ore and 4,271,635 tons of waste. The longer haulage distances and higher lifts resulting from the development of the open pit probably will require new haulage equipment within the next few years. No major construction work was undertaken in 1944.

Amole district.—About 200 tons of gold-silver-lead ore from the waste-dump of the Old Yuma property were treated by concentration in 1944, and 224 tons of similar ore were shipped to a smelter. The rest of the district output was 42 tons of lead ore produced from the Twin Hill claim 22 miles west of Tucson.

Baboquivari district.—Lessees worked the Papago Chief mine from January through April 1944 and shipped 947 tons of high-silica gold-silver-copper ore to the smelter at Hayden. Operations were not profitable, and the lease terminated May 1.

Cerro Colorado district.—About 400 feet of drifting were done at the Mary "G" mine in 1944, resulting in shipments of 2 cars (73 tons) of silver-lead ore.

Helvetia (Rosemont) district.—Of the total ore (20,240 tons) produced in the Helvetia district in 1944, 19,589 tons were copper ore shipped to a smelter; nearly all the remainder was zinc-lead ore (347 tons) and zinc-copper ore (288 tons) shipped to a custom milling plant. The chief producers of copper ore were the Mohawk (10,086 tons), Copper World (5,387), Newman (1,347), Rosemont (1,336), and Bulldozer (1,077 tons); 347 tons of zinc-lead ore and 121 tons of copper ore were produced from the Daylight mine and 288 tons of zinc-copper ore from the Rosemont property.

Old Hat district (Oracle).—The Control Mines Co. operated the Geeseman mine and 100-ton mill continuously throughout the year; approximately 13,700 tons of copper ore were treated by flotation and 44 tons of similar ore shipped to a smelter. Copper ore (1,593 tons) was produced also from the Daily mine, which adjoins the Geeseman property, by the Daily Mines Co. and treated in the Control Mines Co. mill.

Pima (Sierritas, Papago, Twin Buttes) district.—The output of ore and the production of silver, copper, lead, and zinc in the Pima district were much greater in 1944 than in 1943, resulting from a full-year operation of the San Xavier property by the Eagle-Picher Mining & Smelting Co.; mining and milling operations at the property were begun in September 1943. During the summer months the company increased the capacity of its flotation mill from 150 to 350 tons of ore a day so as to treat custom ores. In 1944 the mill treated 52,136 tons of zinc-lead ore from the San Xavier mine and 18,337 tons of custom ores, which yielded 204 tons of copper concentrates, 6,213 tons of lead-copper concentrates, and 13,945 tons of zinc concentrates. The ore from the San Xavier mine averaged 3.52 ounces of silver to the ton, 0.75 percent copper, 6.22 percent lead, and 12.90 percent zinc. The rest of the district output was principally 1,426 tons of zinc ore from the San Xavier Extension mine and 1,111 tons of zinc-copper ore from the Contention mine treated in custom mills.

Roskrige and Waterman (Silver Hill) district.—A. R. Byrd, Jr., operated the Silver Hill mine continuously in 1944 and shipped 4,656 tons of crude copper-silver ore to various smelters in Arizona.

Silver Bell district.—The old Silver Bell mine 40 miles northwest of Tucson was worked by a lessee a short time in 1944, and 96 tons of silver-lead-copper ore were shipped to the smelter at El Paso.

PINAL COUNTY

Bunker Hill district (Copper Creek).—O. W. Blevins operated his Magma Chief group of claims near Sombrero Butte throughout the year and shipped 808 tons of copper ore to the smelter at Hayden; copper ore (34 tons) was shipped from the Mammoth Butte mine also.

Martinez Canyon district.—The California Steel Products Co. continued in 1944 to develop its Silver Bell-Martinez group 8 miles northeast of Price and shipped 423 tons of oxide lead ore to the smelter at El Paso.

Mineral Creek district (Ray).—Underground mining of copper ore at the Ray property of the Kennecott Copper Corporation was at a lower rate in 1944 than in 1943, resulting in a decrease in the output of ore from 2,351,900 to 1,893,683 tons. The crude ore, averaging 24.64 percent copper, was hauled by rail 26 miles to the company 500-ton flotation mill at Hayden, where it was reduced to 96,112 tons of copper concentrate. In addition, 4,850 tons of copper precipitates were shipped to various smelters. At the Ray property, the shortage of labor affected the output of ore even more seriously than at other Kennecott properties, as it was more difficult to secure employees for underground work than for open-pit operations. With the limited personnel available, development also had to be heavily curtailed and did not pace ore extraction.

Nearly all the remaining district output was crude oxide copper ore (5,136 tons) produced from an open pit at the Copper Butte property.

Old Hat district (Oracle).—Mining and milling were continuous at the Mammoth-Collins and New Year-Mohawk groups until September 4, when a fire destroyed the Mohawk shaft, gallows frame, hoist room, ore bins, and other structures. However, by the end of November the property was again producing as the shaft had been repaired and the surface structures completely rebuilt. During the year 42,409 tons of sulfide zinc-lead ore and 27,493 tons of oxide gold-silver-lead-molybdenum-vanadium ore were treated in the company 500-ton milling plant; the oxide ore was treated by gravity concentration, followed by flotation (flotation tailings were cyanided), and the sulfide ore was treated by straight flotation. The oxide lead concentrates (834 tons) were smelted in the company 20-ton lead furnace; and the sulfide lead concentrates (5,408 tons) and the sulfide zinc concentrates (5,896 tons), along with some high-grade gold-iron concentrates (48 tons), were shipped to smelters in Texas. Gold precipitates, as well as molybdenum and vanadium products and lead bullion, were shipped East. In addition, 1,507 tons of crude high-grade lead ore and 15 tons of mill cleanings were shipped to the smelter at El Paso. Mining and milling of oxide ore ceased temporarily July 31, as the company decided to confine its operations to the mining and milling of sulfide zinc-lead ore. The property was the largest producer of lead in Arizona in 1944 and ranked fifth in zinc.

A large deposit of copper-bearing material at a group of 21 claims known as the San Manuel, 1 mile south of Tiger, was examined in 1944 by the Federal Bureau of Mines and Federal Geological Survey. During the year the Magma Copper Co. secured an option to purchase the group, and according to the company annual report for 1944 the Bureau of Mines drilled 14 test holes and is continuing on 2 additional holes. This work indicated the possible presence of a large tonnage of copper-bearing rock which may average 0.7 to 1.0 percent copper.

The wide spacing of the churn-drill holes and the small outcrop or surface exposure of mineralization makes it impossible to determine the tonnage and grade of the deposit. The copper so far seen is mainly in the form of silicates and silicates and sulfides mixed; ore of this type presents a difficult metallurgical problem.

Pioneer district (Superior).—Mining operations at the Magma mine of the Magma Copper Co. were at a much lower rate in 1944 than in 1943, resulting in a decrease in output of ore from 414,183 to 305,262 tons. The company reported that 172,210 tons of copper ore and 88,849 tons of zinc-copper ore were treated in its 850-ton concentrator, and 44,203 tons of crude copper ore along with 60,450 tons of copper concentrates recovered from copper ore and 11,541 tons of copper concentrates recovered from zinc-copper ore were sent to the company 450-ton smelter at Superior. The zinc concentrates (8,456 tons) were shipped to Amarillo, Tex. The mill was operated 7 days a week until August 1 and 6 days a week thereafter.

According to the company printed annual report for 1944, the net metal produced from Magma ore and concentrates was 7,045 ounces of gold, 283,088 ounces of silver, 23,502,347 pounds of copper, and 7,333,007 pounds of zinc. The average net cost of producing copper after deduction of gold, silver, and zinc concentrate values was 12.48 cents a pound in 1944 compared with 10.28 cents in 1943. The decrease in production of gold, silver, copper, and zinc was the major cause of the greatly increased costs. The labor situation, bad in 1943, became progressively worse in 1944; during the latter half of the year the labor shifts actually worked were approximately 60 percent of those necessary for full production. The output of ore dropped from 34,872 tons in January to 15,203 tons in December. Copper ore was stoped from the 4,400 level to the 3,200 level. At the end of the year no known ore was left on the west side of the mine above the 3,400 level, and mining of copper ore was confined to the 4,000, 3,800, and 3,600 levels. Zinc-copper ore was stoped from the 2,250 level to above the 1,500 level on the east side of the mine. Development in 1944 comprised 2,927 feet of drifting, 2,610 feet of raising, 642 feet of crosscutting, and 114 feet of sinking.

The remainder of the district output was principally 1,370 tons of crude siliceous silver ore produced from the Reymert mine by Reymert Lease.

Summit district.—Haddy & Nelson leased the American Mines property west of Miami in 1944 and shipped 171 tons of copper ore to the International smelter at Miami.

SANTA CRUZ COUNTY

Harshaw district.—The American Smelting & Refining Co. operated the Trench and Flux groups 12 miles south of Patagonia continuously throughout the year and in October took over the January property. The total output from the three properties was 49,393 tons of zinc-lead-silver ore, which was treated in the company 200-ton flotation mill; however, the production of silver, lead, and zinc was much less than in 1943. The American Smelting & Refining Co. also operated the Hardshell mine throughout the year and shipped 1,295 tons of oxide silver-lead ore to the smelter at El Paso. The rest of the district output was nearly all siliceous silver ore (52 tons) produced from the Salvador claim.

Oro Blanco district (Ruby).—Mining of highly siliceous silver ore

was carried on at the Brick claim from January through August; 546 tons of ore of this class were shipped to various smelters in Arizona.

Palmetto district.—Pierce & Bird operated the old Three "R" mine 12 miles southwest of Patagonia throughout the year and shipped 4,162 tons of sulfide copper ore to the smelter at El Paso.

Patagonia (Duquesne) district.—Mining and milling zinc-lead-copper ore at the Duquesne property of the Callahan Zinc-Lead Co. were continuous until July 30, when operations ceased permanently; later the company moved its 140-ton mill to a property in Nevada. During the year 14,578 tons of ore from this mine were treated by flotation. In addition, the mill treated 2,326 tons of zinc-copper ore from the Pride of the West mine operated by the Humphrey Mining Co. The total output from the mill was 907 tons of copper concentrates, 234 tons of high-grade silver-lead concentrates, and 2,432 tons of zinc concentrates. Besides the zinc-copper ore produced from the Pride of the West mine and treated in the Duquesne mill, the mine also produced 1,284 tons of zinc lead ore which was treated in the Trench mill. The remainder of the district output comprised 909 tons of lead ore produced from the Mowry mine and 294 tons of copper ore from the Gladstone and Roy properties.

Tyndall district.—A total of 262 tons of ore was produced in the Tyndall district in 1944; most of it was silver-lead ore (141 tons) shipped to smelters from the Alto, Jefferson, and San Ramon properties, and copper ore (103 tons) from the Bland and Half Moon claims.

YAVAPAI COUNTY

Agua Fria district.—The total output in the Agua Fria district in 1944—11,917 tons of ore—was high-silica copper ore shipped direct to a smelter; 7,219 tons was produced from the Binghamton mine 6 miles east of Mayer, 3,906 tons from the Stoddard mine, 757 tons from the Burzog (Old Minor) property, and 35 tons from the Yaller Kid claim.

Big Bug district.—A total of 112,441 tons of ore and old tailings was produced in the Big Bug district in 1944, compared with 82,312 tons of ore and old tailings in 1943. The most important output was, as in 1943, zinc-lead ore (98,988 tons) from the Iron King mine at Humboldt treated by flotation. In addition, 170 tons of gold-silver ore were shipped direct to a smelter. The Shattuck Denn Mining Corporation operated the mine and its 325-ton (increased during 1944 from 240 tons of ore a day) flotation mill continuously throughout the year. The mill treated 103,231 tons of ore (including 4,243 tons of custom ores) in 1944, which yielded 4,430 tons of lead concentrates, 8,910 tons of zinc concentrates, and 5,290 tons of iron concentrates. About 8,000 tons of old copper tailings from the Humboldt tailing dump were treated by flotation. The rest of the district lode output was 4,000 tons of zinc-lead-copper ore from the Hackberry mine treated in the Iron King custom mill and 1,283 tons of copper ore from the Blue Bell mine shipped to the smelter at Clarkdale. The placer output was 202 ounces of gold and 21 ounces of silver recovered by sluicing at the Standard claim near Mayer.

Black Canyon district.—Lessees operated the French Lilly mine near Cleator in 1944 and hauled 123 tons of zinc-copper ore to the Iron King custom mill. The rest of the district output was mainly 121 tons of highly siliceous gold ore produced from an open pit at the Golden Turkey property and shipped direct to a smelter.

Black Hills district.—The Shylock mine near Dewey was operated a short time in 1944; 125 tons of siliceous silver-copper ore were shipped to the smelter at Clarkdale, and 4 tons of similar ore were produced from the Yaeger claim.

Black Rock district.—Virtually all the output of 101 tons of ore in the Black Rock district in 1944 was copper ore produced from the Bloo Nelly (Unida) mine, 10 miles north of Wickenburg.

Bullard (Pierce) district.—Mining operations at the Bullard mine near Aguila by Bullard Gold Mines, Inc., were continuous throughout the year; the company shipped 7,500 tons of siliceous gold-copper ore to smelters in Arizona.

Copper Basin district.—Fred D. Schemmer operated the Commercial mine near Skull Valley continuously in 1944 and shipped 15,527 tons of low-grade siliceous copper ore to the smelter at Clarkdale. The remainder of the district output was 111 tons of crude zinc ore produced from the Boston-Arizona mine and hauled to a custom flotation mill at Humboldt.

Eureka district.—Mining and milling of copper ore at the Bagdad property of the Bagdad Copper Corporation were at a much greater rate in 1944 than in 1943. The company reported that 668,887 tons of copper ore (375,715 tons in 1943) were treated in its 2,500-ton flotation plant and that 11,298 tons of concentrates averaging 43.70 percent copper were shipped to the smelter at El Paso. In addition, some molybdenum concentrates were sold to the Molybdenum Corporation of America. The rest of the district output was mainly 592 tons of zinc oxide ore, 446 tons of zinc-lead ore, and 216 tons of copper ore shipped to various reduction works from the Copper King mine and 802 tons of copper ore from the Eureka and Old Dick properties.

Hassayampa (Groom Creek, Hassayampa River, Senator, Prescott) district.—The principal output in the Hassayampa district in 1944 was 416 tons of copper ore from the Van Hook and Treadwell properties near Prescott and 34 tons of lead ore from the Bodie mine.

Martinez (Congress) district.—Mining operations in the old gold district of Martinez in 1944 were insignificant compared with earlier years; the only output in 1944 was 33 tons of gold ore from the Congress mine and 13 tons of copper ore from the Senate mine.

Pine Grove district (Crown King).—Lessees operated the Springfield mine from March through December and shipped 1,952 tons of siliceous copper ore to the smelter at Clarkdale. The remainder of the district output comprised 900 tons of zinc-lead-gold ore treated in a flotation mill and 565 tons of gold ore shipped direct to a smelter from the Gladiator-War Eagle group by the Gladiator Mining Co.

Tiger district.—Leasing operations at the Pilgrim claim near Crown King in 1944 resulted in the shipment of 5 cars (216 tons) of rich gold ore.

Verde district (Jerome).—Copper ore mined from the underground workings of the United Verde property of the Phelps Dodge Corporation continued in 1944 to be the most important output in the Verde district; however, production decreased from 879,170 tons in 1943 to 503,620 tons in 1944. Of the ore mined in 1944 from the property 150,506 tons was siliceous copper ore shipped to the corporation smelter at Clarkdale and 353,114 tons was similar ore treated in the corporation 2,100-ton concentrator. In addition, 365 tons of copper precipitates were shipped to the smelter.

According to the annual report of the corporation for 1944, the decline in tons of ore mined resulted from a shortage of labor and from

a depletion of ore reserves. By the end of the year all minable ore, with the exception of the shaft pillars, was exhausted above the 1,800 level. Development totaled 40,895 feet, comprising 4,968 feet of drifting, 1,027 feet of raising, 370 feet of calyx drill holes, and 34,530 feet of diamond drilling. Practically all of this work was for exploratory purposes in the deep levels of the mine; the results were disappointing, and no tonnage of economic importance was added to the ore reserves.

The rest of the district output comprised 11,452 tons of siliceous gold-silver ore from the Iron King-Equator group, shipped by lessees to the smelter at Clarkdale, and 10,191 tons of siliceous copper ore shipped to a smelter from the Dundee-Arizona, Florentia, and Verde properties.

Walker district.—The principal output in the Walker district in 1944 was 379 tons of high-grade gold-lead ore produced from the Emma and Oro Plata properties and shipped to a smelter.

Weaver district (Octave).—Lessees worked the Monica mine a short time in 1944 and shipped 28 tons of highly siliceous gold ore to the smelter at Hayden. The remainder of the district output was 4 tons of old mill cleanings (valued chiefly for gold) and 3 ounces of placer gold.

White Picacho district.—The output of the White Picacho district in Yavapai County in 1944 comprised 210 tons of gold-copper ore produced from the Jumbo group, 14 tons of silver-lead ore from the Independence mine, and 6 tons of gold ore from the Vanadium claim.

YUMA COUNTY

Castle Dome district.—Mining and milling of lead ore at the De Luce group by the Arizona Lead Co. were continuous throughout the year. The company treated 16,382 tons of oxide lead ore in its 150-ton mill, equipped with jigs and tables, and shipped 42 tons of high-grade oxide lead ore to the smelter at El Paso. The rest of the district output was 9 ounces of gold and 69 ounces of silver recovered from gravel at the Ocatilla placer.

Cienega district.—The principal output of the Cienega district in 1944 was 1,293 tons of highly siliceous gold-copper ore produced from the Empire-Arizona property, 12 miles east of Parker, by Strategic Metal Mines.

Ellsworth (Harqua Hala) district.—Low-grade gold-copper ore (2,839 tons) mined from the Yuma Copper mine near Vicksburg by the Liberator Mines Co. was virtually all the output in the Ellsworth district in 1944.

Never Sweat district.—Lessees worked the Addie property north of Bull in 1944 and shipped 85 tons of lead ore to the smelter at El Paso.

Plomosa district.—The Little Butte mine, 4 miles southwest of Bouse, was operated (under lease) throughout the year by the New World Mining Co., which shipped 768 tons of low-grade gold-copper ore and 126 tons of fairly rich gold ore to various smelters in Arizona. The remainder of the district output was largely 698 tons of siliceous silver ore and 165 tons of siliceous silver-lead ore produced from the R. & A. mine by various lessees.

Santa Maria (Planet, Bill Williams) district.—During the first 6 months of 1944 the Swansea Development Co. continued to operate (under lease) the Swansea mine and shipped 1,072 tons of copper ore to the smelter at Hayden. At the end of June the mine was shut down and the lease canceled.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN CALIFORNIA

(MINE REPORT)

By CHARLES WHITE MERRILL

SUMMARY OUTLINE

	Page		Page

SUMMARY

California gold production in 1944 fell below that in any year since 1848—the year James A. Marshall made his historic discovery in the gravels of the American River near Coloma. Silver production, though 28 percent higher than in 1943, otherwise was the lowest since 1933 in quantity and 1934 in value. However, copper production was the largest in both quantity and value since 1930; zinc was the largest in quantity since 1926 and in value since 1916; and lead, though 2 percent smaller in quantity than in 1943, was larger in value than in any year since 1918. The total value of the five metals (\$10,933,-495), though 19 percent higher than in 1943, was otherwise the lowest since 1848. Higher wages, enlistment of miners in the armed forces, migration of miners to war industries, rising prices of supplies and equipment and difficulties in obtaining them, increased taxes, and the fixed prices of gold and silver were factors accelerating the downward trend, which was already under way in 1942. In addition, throughout 1943 and 1944, War Production Board Limitation Order L-208 (promulgated October 8, 1942) prevented all larger gold operations except under special grant. California gold miners were issued grants as follows: During 1942, 18; during 1943, 27; and during 1944, 25; none was rescinded. Thus of the 119 grants issued to domestic gold miners, California producers received 70 and those in all other States 49.

Comparing 1944 with 1943, gold decreased 21 percent but silver increased 28 percent in both quantity and value; copper increased 45 percent in quantity and 51 percent in value; lead decreased 2 percent in quantity but increased 4 percent in value; and zinc increased 356 percent in quantity and 381 percent in value. The total value of the five metals was 19 percent more than in 1943; of the total value gold represented 38 percent, copper 31 percent, zinc 18 percent, lead 8 percent, and silver 5 percent.

The counties of the State, arranged by value of output of the 5 metals, were in very different order in 1943 and 1944 from preceding

years, because in these latter years it was base-metal output that raised counties to leadership, whereas in earlier years the counties at the top of the list were invariably big gold producers. Siskiyou County, second on the list in 1943 and eighth in 1942, was the leader in 1944 owing almost entirely to the copper output of the Dakin mine, Mammoth River district, operated by the Gray Eagle Copper Co. Elko County, second on the list in 1944, was first in 1943 but seventh in 1942; lead represented over half of the total value of its metal output, and the value of each of the other 4 metals was also substantial. Mariposa County, third on the list in 1944, owed its position largely to the zinc production of the Blue Moon mine, Hunter Valley district, operated by Red Cloud Mines, Inc. Calaveras County was fourth on the list in 1944, with operations along the Mother Lode and in the

FIGURE 1.—Value of mine production of gold, silver, and copper and total value of gold, silver, copper, and zinc in California, 1848-1944. The value of lead and zinc has exceeded \$1,000,000 in only a few years.

East Belt largely suspended but copper and zinc-copper mines west of the Mother Lode reporting large outputs. Yuba County, which had been in third place in 1942 and 1943 largely as the result of gold output of its connected-bucket gold dredges, dropped to fifth place in 1944 despite the War Production Board grant permitting the working of 2 of the large dredges in the Yuba Consolidated Gold Fields' fleet of 6 boats. Other counties of the leading 10, listed in order of total value of output, were: Shasta County (largely from copper-zinc ore), Sacramento County (almost entirely from connected-bucket dredging), Butte County (largely from connected-bucket dredging and some zinc ore), Nevada County (largely from gold ore), and Tuolumne County (largely from gold ore of the Eagle Shawmut mine). Of the 30 counties producing, these 10 furnished 92 percent of the total value of the five metals produced in the State during the year.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.7114	\$0.113	\$0.050	\$0.093
1941.....	35.00	0.7114	.118	.057	.075
1942.....	35.00	0.7114	.121	.067	.093
1943.....	35.00	0.7114	.130	.075	.108
1944.....	35.00	0.7114	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Company for overquota production.

⁴ \$0.71111111.

Mine production of gold, silver, copper, lead, and zinc in California, 1940-44, and total, 1848-1944, in terms of recovered metals

Year	Mines producing ¹		Ore, old tailings, etc. (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value

¹ For historic data by years see Minerals Yearbook, Review of 1940, p. 219.

² Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

³ First year for which this method was reported used in California.

⁴ Includes all placer operations using suction pump for delivering gravel to floating washing plant, except those producing less than 100 ounces of gold which are included under "Small-scale hand methods."

⁵ Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."

⁶ Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dry boxes, pans, rockers, dry washers, etc.

⁷ From property not classed as a "mine."

⁸ A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.

⁹ Complete data not available.

*Gold.*¹—An uninterrupted rise beginning in 1929 culminated in the production of \$50,948,485 in gold in 1940, the largest value since 1856. In 1941, however, a reaction set in that gained headway in 1942. By January 1943 monthly production had sunk to 16,425 fine ounces, and since that time it has fluctuated between that figure and a low of 8,547 ounces established in February 1943. The monthly fluctuations were narrower during 1944; the monthly average for the year was 9,781 ounces compared with a monthly average of 12,361 ounces for 1943. Compared with 1942, the decrease of 699,669 ounces (\$24,488,415) recorded in 1943 was greater in both quantity and value than that between any other 2 years in the State's history, not excluding 1852-53, 1854-55, and 1856-57, when flush placer output was failing; 1883-84, when the Sawyer Decision drastically reduced hydraulicking; and 1917-18, when World War I caused many operations to suspend or curtail output. The decrease of 30,955 ounces valued at \$1,083,425 in 1944 from 1943 seems small when the decrease of the 2 preceding years is considered.

Mine production of gold in California, 1937-44, by months, in fine ounces, in terms of recovered metal

A study of the monthly production figures since January 1937 brings out some points that are obscure in the annual figures. The uninterrupted upward trend shown in the annual figures beginning in 1929 and culminating in 1940 is paralleled in the available monthly data. It will be noted, however, that a serious recession was experienced in July 1940 from which industry did not fully recover until November. This was caused by a labor strike at the Selby smelter and refinery of the American Smelting & Refining Co., which resulted in the postponement of many shipments of ore, concentrates, and bullion; the strike was called July 1, and work was resumed November 9. The peak reached in December 1940 may be attributed, at least in part, to the movement of material accumulated during the strike. Beginning with January 1941, however, the trend is unmistakably downward, and the rate of decline accelerates as the months pass. The downward plunge is arrested in October 1942 probably because many operations, closed by War Production Board Order L-208, made final clean-ups, which were shipped before the end of the month. At any rate, the decline in November and December 1942 put the curve back on the precipitous trend line shown during the few months pre-

¹ Not operated in 1943.

ceding October. By January production had reached a level that permitted little further recession, and this low level has ruled throughout 1943 and 1944 with only a slight additional decline.

The 25 leading gold-producing mines in California in 1944, listed in the foregoing table, yielded 90 percent of the total gold output of the State; the leading 5 mines produced 62 percent and the leading 10 mines 79 percent. Many changes have taken place in the list since 1943; and only 8 of the mines listed in 1942 are on the 1944 list.

FIGURE 3.—Percentage of total California gold produced at lode and placer mines and by various methods of placer mining, 1850-1944.

Silver.—Most of the silver output in California in 1944 was more localized than that of the gold; the 10 leading silver-producing mines listed in the following table yielded 82 percent of the State total recoverable silver in that year, and the 4 leading mines yielded 62 percent. All 10 leading mines derived their silver from argentiferous base-metal ores.

Ten leading silver-producing mines in California in 1944, in order of output

Rank	Mine	District	County	Rank in 1943	Operator	Source of silver
1	Darwin group	Coso	Inyo	2	Darwin Mines (Arthur J. Theis, trustee).	Lead ore.

5		Coso	Inyo	32	Louis Warnken, Jr.	Lead ore.
6	Pine Creek	Bishop Creek	do	4	United States Vanadium Corp.	Tungsten-molybdenum ore.
7	Penn	Campo Seco	Calaveras	(¹)	Eagle Shawmut Mine (Penn Division).	Zinc ore.
8	Quall Hill	West Belt	do	7	G. Ivan Smith	Do.
9	Silverado	Santa Rosa	Orange	(¹)	Blue Light Silver Mines Co.	Do.
10	Last Chance	Coso	Inyo	6	L. D. Foreman & Co.	Lead ore.

¹ Not operated in 1943.

Copper.—Copper production in California in 1944 was the largest in both quantity and value since 1930. Most of the copper came from mines brought into production since 1942. The following 11 companies, listed in order of copper output and each producing more than 100,000 pounds, supplied 98 percent of the State total and the first three 87 percent: Gray Eagle Copper Co. (Dakin mine, Klamath River district, Siskiyou County); Keystone Copper Corp. (Keystone mine, Copperopolis district, Calaveras County); The Mountain Copper Co., Ltd. (Hornet mine, Flat Creek district, Shasta County); Pacific Mining Co. (Union mine (old tailings), Copperopolis district, Calaveras County); Hoefling Bros. (Big Bend mine, Yankee Hill district, Butte County); Winston Copper Co. (Newton mine, Ione district, Amador County); United States Vanadium Corp. (Pine Creek mine, Bishop Creek district, Inyo County); Eagle Shawmut Mine (Penn mine, Campo Seco district, Calaveras County); L. D. Foreman & Co. (Copper World smelter site (old slag dump), Clark Mountain district, San Bernardino County); G. Ivan Smith (Quail Hill mine, West Belt district, Calaveras County); and Red Cloud Mines, Inc. (Blue Moon mine, Hunter Valley district, Mariposa County).

Lead.—Lead production in California in 1944 was slightly smaller than in 1943, but its value exceeded that in any year since 1918. The two leading producers contributed over 67 percent of the State total in 1944. The following nine companies, listed in order of lead output and each producing over 100,000 pounds, furnished 94 percent of the State total: Darwin Mines (Essex and Independence mines, Coso district, Inyo County); Shoshone Mines, Inc. (Columbia No. 2 mine, Resting Springs district, Inyo County); Damon & Damon (Gold Bottom and Ophir mines, Slate Range district, Inyo County); L. D. Foreman & Co. (Last Chance (slag dump), Coso district, Inyo County); Louis Warnken, Jr. (old tailings, Coso district, Inyo County); Clayton T. McNeil & C. Erb Wuensch (old flue dust, Flat Creek district, Shasta County); Imperial Metals, Inc. (Cerro Gordo mine, Cerro Gordo district, Inyo County); Dunton-Ray & Greenwood (Mohawk mine, Clark Mountain district, San Bernardino County); and Red Cloud Mines, Inc. (Blue Moon mine, Hunter Valley district, Mariposa County).

Zinc.—Zinc production in California in 1944 was the largest in quantity since 1926 and in value since 1916. Most of the output came from mines brought into production since 1942. The following 12 companies, listed in order of zinc output and each producing over 100,000 pounds, contributed 99 percent of the State total: Red Cloud Mines, Inc. (Blue Moon mine, Hunter Valley district, Mariposa County); Hoefling Bros. (Big Bend mine, Yankee Hill district, Butte County); The Mountain Copper Co., Ltd. (Hornet mine, Flat Creek district, Shasta County); Eagle Shawmut Mine (Penn mine, Campo Seco district, Calaveras County); Darwin Mines (Essex and Independence mines, Coso district, Inyo County); Clayton T. McNeil & C. Erb Wuensch (old flue dust, Flat Creek district, Shasta County); G. Ivan Smith (Quail Hill mine, West Belt district, Calaveras County);

E. A. Vogt (Collier mine, West Belt district, Calaveras County); Damon & Damon (Gold Bottom and Ophir mines, Slate Range district, Inyo County); Dunton-Ray & Greenwood (Mohawk mine, Clark Mountain district, San Bernardino County); Shoshone Mines, Inc. (Columbia No. 2 mine, Resting Springs district, Inyo County); and Southwest Lead & Zinc Co. (Honolulu-Big Horn mine, South Park district, Inyo County).

¹ Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

² Output from property not classed as a "mine."

³ Combined to avoid disclosure of individual output.

MINING INDUSTRY

The tonnage of material from lode mines in California treated in 1944 increased 25 percent compared with 1943, and the yardage at placer mines increased 5 percent; the output of lode gold declined 28 percent and that of placer gold 16 percent. The increase in base-metal ore production more than counterbalanced the decrease in gold-ore output. The average recoverable gold content of gravels decreased 20 percent and was the lowest since 1932. Of the State total gold output in 1944, 36 percent came from lode mines and 64 percent from placers; this represents the highest placer: lode ratio since 1900, when separate annual data were first compiled, and is almost certainly the highest since large-scale hydraulicking was terminated by the Sawyer Decision of 1884.

Dredges of the connected-bucket type washed 92 percent of the total gravel mined in the State in 1944 and recovered 87 percent of the total placer gold; the value of gold produced by connected-bucket dredges was the smallest since 1904, and its quantity was the smallest since 1902. Dragline dredges washed 5 percent of the total gravel mined and recovered 8 percent of the placer gold, the lowest point reached by dragline dredging in either yardage washed or gold recovered since 1934—second year in which the method was used in California.

All other placer-mining methods, except small-scale hand methods (dry), showed decreases in both quantity of gravel washed and gold recovered. No Becker-Hopkins or suction dredges have been reported in production since 1942. Nonfloating washing plants to which gravel was delivered by mechanical means (dragline excavators, power shovels, slackline excavators, trucks, and bulldozers) treated much less gravel and recovered much less gold than in 1943. Many of the operators of such plants found that their equipment could be employed more profitably on war contracts; competition for labor skilled in operating earth-moving machines was very keen.

Hydraulic mining at established mines found itself singularly free from shortages of materials and power, but labor conditions caused marked reductions in operations. Very few hydraulic mines opened for the 1944-45 season. Gold production from small-scale hand methods was sharply curtailed. In normal times a large number of such operations are carried on independently by marginal workers, but the increasing labor shortage in California in 1944 caused many small-scale hand miners to abandon the streams and dry diggings for employment at wages. Drift mining, once very productive in California, also declined owing to war conditions.

Consumption of quicksilver at California placer mines totaled 1,375 pounds in 1944 compared with 2,026 pounds in 1943. The following quantities of gold were recovered to the pound of quicksilver used in 1944 (1943 figures in parentheses): Connected-bucket dredging, 63 ounces (40); dragline dredging, 46 ounces (49); nonfloating washing plants with mechanical gravel handling, 45 ounces (49); hydraulicking, 40 ounces (11); and small-scale hand operations, 9 ounces (23).

ORE CLASSIFICATION

Of the 925,953 tons of ore (including 234,109 tons of old tailings) sold or treated in 1944, 60 percent was copper (two-fifths of which

was old tailings), 14 percent gold, 10 percent zinc-copper, 7 percent zinc, 4 percent lead, 4 percent zinc-lead, and the remainder dry gold-silver and dry silver. Substantial quantities of copper and silver and some gold and lead were recovered from ore valued chiefly for tungsten and molybdenum; this ore is not included in the tonnage figures, but the metals are included in the metal totals.

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in California in 1944, with content in terms of recovered metals

² Excludes metal recovered from tungsten ore.

³ Excludes 61,100 pounds from precipitates.

⁴ Excludes 65,000 pounds from precipitates.

METALLURGIC INDUSTRY

During 1944, 79 percent of the total ore and old tailings handled was treated at concentrating mills, 14 percent was treated at amalgamation and cyanidation mills, and 7 percent was shipped for direct smelting. Smelters also received 86,879 tons of flotation concentrates and 74 tons of gravity concentrates from California mine operators. Comparing 1944 with 1943, material treated at cyanidation mills decreased 86 percent, the quantity of material amalgamated decreased 37 percent, and the quantity of crude ore and old tailings smelted decreased 5 percent. The quantities of ore and old tailings concentrated, however, increased 169 percent; the tonnage of tungsten ore concentrated is not included in 1943 or 1944.

Because of unusual conditions in the California gold industry in 1943 and 1944, quicksilver- and cyanide-consumption data at mills were not representative of the industry.

The Selby lead smelter of the American Smelting & Refining Co. was the only custom plant that treated gold, silver, copper, lead, or zinc ores in California in 1944. Some ore and concentrates were shipped to out-of-State smelters. Most of the ore produced in the State, however, was treated in company-owned metallurgical plants at the mines.

Mine production of metals in California in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc
Ore and old tailings amalgamated	Short tons 125,193	Fine ounces 14,752	Fine ounces 2,722	Pounds	Pounds	Pounds

[illegible]

¹ Only those districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 13 and their output included under "Other districts."

² Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

³ Source of total silver as follows: 774,405 ounces from lode mines and 4,531 ounces from placers.

Counties.
 † Output from property not classed as a "mine."

6 Comanche district lies in Amador, Calaveras, and San Joaquin Counties.
7 East Belt district lies in Amador, Calaveras, El Dorado, Mariposa, and Tuolumne Counties.

Counties.

^a West Belt district lies in Calaveras and Eldorado Counties.
Dandelion district lies in Kern and San Bernardino Counties.

¹⁰ Includes 61,100 pounds from precipitates.

² Exclusive of lode output, which is included under "Other districts."

¹³ Includes following: Bishop Creek and South Park districts in Valley-Nevada City (code) in Nevada County; Exchequer in San

amanche in San Joaquin County; Alleghany (lode) in Sierra County

¹⁴ Excludes tungsten ore.

* Includes metal recovered from tungsten ore.

AMADOR COUNTY

Ione district.—The Winston Copper Co. operated the Newton mine throughout 1944 and shipped 4,327 tons of copper ore containing 29 ounces of gold, 1,966 ounces of silver, and 483,488 pounds of copper to a smelter.

Mouher Lode district.—The Nevada Wabash Mining Co. undertook development at the Nevada Wabash mine on February 15, 1944, and treated gold ore by amalgamation. The Central Eureka Mining Co. recovered a small quantity of gold from a mill clean-up at the Old Eureka and Central Eureka mines.

BUTTE COUNTY

Oroville district.—The Golden Feather Dredging Co. operated a dragline dredge on the Feather River channel at Oroville during 1944, but work was suspended before the end of the year; an electric dragline excavator equipped with a 5-cubic yard bucket was used. This operation was carried on under a special grant from the War Production Board because gravel cleared from the Feather River channel was stacked as a levee to protect the town of Oroville. The Morris Ravine Mining Co. produced 1,100 cubic yards of gravel at the Morris Ravine drift mine while maintaining the property for postwar operation; 181 ounces of gold and 18 ounces of silver were recovered. The Oroville Gold Dredging Co. operated a connected-bucket dredge equipped with 72 $8\frac{1}{2}$ -cubic foot buckets on Feather River 9 miles southwest of Oroville from January 1 to November 2.

Yankee Hill district.—Hoeftling Bros. operated the Big Bend mine throughout 1944 and trucked 14,297 tons of zinc ore to the Surcease mill, which had been converted from a gold mill to treat Big Bend ore; 701 tons of copper concentrate (containing 215 ounces of gold, 1,932 ounces of silver, 360,485 pounds of copper, 28,928 pounds of lead, and 290,100 pounds of zinc) and 2,702 tons of zinc concentrate (containing 348 ounces of gold, 8,965 ounces of silver, 189,013 pounds of copper, 26,983 pounds of lead, and 3,003,115 pounds of zinc) were recovered by flotation and shipped to smelters. The company carried on extensive exploration in the area.

CALAVERAS COUNTY

Campo Seco district.—Eagle Shawmut Mine completed the unwatering of the Penn mine in October 1943 and began shipping zinc-copper ore to the company mill at the Eagle Shawmut mine near Jacksonville in May 1944. Production was increased progressively during 1944, but further expansion was still in prospect at the end of the year. A section of the Eagle Shawmut gold mill was reequipped to treat the Penn mine ore.

Copperopolis district.—The Keystone mine was operated throughout 1944 by the Keystone Copper Corp., successor to the Keystone Copper Co.; 98,578 tons of copper ore were trucked to the nearby redesigned Mountain King flotation mill, and 7,364 tons of copper concentrates containing 54 ounces of gold, 3,195 ounces of silver, and 3,836,700 pounds of copper were shipped to a smelter. The company was the second-largest copper producer in the State, as in 1943. The Pacific Mining Co. operated a flotation plant on old tailings at the Union mine throughout 1944. The quantity of material treated and the recovery of copper concentrate increased progressively during the year.

Jenny Lind district.—Lessees amalgamated gold ore that was produced at the Royal mine during 1944.

Mother Lode district.—Clean-up material at the Carson Hill operation yielded a small quantity of gold.

West Belt district.—E. A. Vogt worked the Collier mine from January 1 to July 15; 2,604 tons of zinc ore were shipped to a concentrator smelter. The ore contained 220 ounces of gold, 9,949 ounces of silver, 7,799 pounds of copper, 52,579 pounds of lead, and 568,491 pounds of zinc. G. Ivan Smith worked the Quail Hill mine until operations were suspended near midyear. Zinc ore was shipped to a concentrator smelter.

ELDORADO COUNTY

Mother Lode district.—Pioneer-Lilyama Mines carried on a mine-development and mill-construction program at the Pioneer-Lilyama mine; 1,400 tons of copper ore were treated in the 250-ton flotation mill, and 93 tons of concentrates containing 30 ounces of gold, 623 ounces of silver, and 54,028 pounds of copper were shipped to a smelter.

FRESNO COUNTY

Friant district.—The Grant Service Rock Co., Consolidated, recovered 155 ounces of gold and 18 ounces of silver in preparing 189,458 tons of sand and gravel for concrete aggregate.

INYO COUNTY

Bishop Creek district.—The United States Vanadium Corp. produced, by flotation, a copper concentrate containing a substantial quantity of silver per ton as a byproduct from ore treated primarily for tungsten.

Cerro Gordo district.—Imperial Metals, Inc., conducted an exploration and development campaign at the Cerro Gordo mine throughout 1944 and shipped argentiferous lead ore to a smelter; the work was under the direction of the management of the Golden Queen Mining Co.

Coso district.—The Darwin group of mines, which includes the Defiance, Independence, Essex, Thompson, Lucky Jim, Lane, Promontory, and Columbia claims, was operated by Darwin Mines (Arthur J. Theis, trustee) throughout 1944; 27,237 tons of lead-zinc ore were treated in the company 125-ton flotation mill, and 1,186 tons of lead concentrate (containing 52 ounces of gold, 53,037 ounces of silver, 13,123 pounds of copper, 1,175,081 pounds of lead, and 5,377 pounds of zinc) and 1,351 tons of zinc concentrate (containing 16 ounces of gold, 11,606 ounces of silver, 10,680 pounds of copper, 140,180 pounds of lead, and 1,232,322 pounds of zinc) were shipped to a smelter. In addition, 10,883 tons of lead ore containing 106 ounces of gold, 126,714 ounces of silver, 40,796 pounds of copper, and 2,883,034 pounds of lead were shipped for direct smelting. Company operations were curtailed by a chronic labor shortage. L. D. Foreman & Co. shipped material to a smelter from the Last Chance old slag dump and from the Wallace old slag dump. Louis Warnken, Jr., shipped old tailings to a smelter.

Resting Springs district.—Shoshone Mines, Inc., operated the Columbia No. 2 mine throughout 1944; 14,593 tons of lead ore containing 1,810 ounces of gold, 92,818 ounces of silver, 31,634 pounds of copper, 3,701,492 pounds of lead, and 1,959,480 pounds of zinc were shipped to smelters.

Slate Range district.—Damon & Damon worked the Gold Bottom and Ophir mines throughout 1944; 1,163 tons of gold-silver ore and 1,326 tons of gold-silver old tailings (containing 171 ounces of gold, 4,113 ounces of silver, 21,090 pounds of copper, and 178,483 pounds of lead) and 3,473 tons of zinc-lead ore (containing 62 ounces of gold, 5,500 ounces of silver, 10,018 pounds of copper, 477,756 pounds of lead, and 523,096 pounds of zinc) were shipped to a smelter. The moving of the Mineral Reduction Co. cyanide-flotation mill from Benton Station and its reconstruction at the Ophir mine as a 150-ton concentration and flotation mill were continued during the year.

South Park district.—The Southwest Lead & Zinc Co. operated the Honolulu-Big Horn (Gibraltar) mine in 1944 from January 1 until August, when the property was quitclaimed to its owner, Frank Long.

Union district.—T. L. Bright shipped gold ore to a smelter from the Reward (Brown Monster) mine.

Wild Rose district.—Silas Ness shipped zinc-lead ore from the Big Four mine to a smelter.

KERN COUNTY

Amalie district.—The Pacific-Atlantic Metals Corp. reopened the Black Hawk mine in Stud Horse Gulch during 1944 and shipped a small quantity of zinc-lead ore to a smelter; operations were suspended before the end of the year.

Green Mountain district.—Mattie Moreland amalgamated ore from the Lone Star mine during an operating period from May 1 to October 27, 1944.

Mojave district.—During a brief operating period Burton Bros., Inc., cyanided a small quantity of gold ore from the Tropico mine.

Randsburg district.—The Butte Lode Mining Co. cyanided 2,846 tons of old tailings in the Butte Lode mine, from which 145 ounces of gold and 47 ounces of silver were recovered.

LOS ANGELES COUNTY

San Gabriel district.—The Consolidated Rock Products Co. recovered gold and silver as byproducts from its Largo Plant No. 10 gravel-washing operation. Robert A. Riggs recovered 29 ounces of gold and 4 ounces of silver as byproducts in the preparation of sand and gravel for concrete aggregate.

MADERA COUNTY

Daulton district.—The West Lode Reduction Co. recovered copper cement containing 61,100 pounds of copper from mine water pumped from the Daulton mine during operations from January 1 to December 12, 1944.

MARIPOSA COUNTY

East Belt district.—A. E. Clark worked the Our Chance mine from January 14 to April 1 and recovered 54 ounces of gold and 10 ounces of silver from 165 tons of ore amalgamated. Schroeder, Odgers, &

Schroeder worked the Schroeder group throughout 1944 and amalgamated 196 tons of ore with a recovery of 320 ounces of gold and 6 ounces of silver.

Hunter Valley district.—Lessees worked the B. A. B. (Akcoz) mine throughout 1944 and shipped 82 tons of gold-silver ore containing 36 ounces of gold, 1,052 ounces of silver, and 43 pounds of copper to a smelter. Red Cloud Mines, Inc., an operating subsidiary of the Idaho Mining Co. of Wallace, Idaho, worked the Blue Moon mine throughout the year; 34,267 tons of zinc ore treated in the company flotation mill (a converted and enlarged gold mill formerly used to treat gold ore from the Jenny Lind mine) yielded 761 tons of gold-copper concentrate containing 1,013 ounces of gold, 69,798 ounces of silver, 186,902 pounds of copper, 243,216 pounds of lead, and 319,780 pounds of zinc and 6,988 tons of zinc concentrate containing 880 ounces of gold, 43,775 ounces of silver, 48,440 pounds of lead, and 6,435,300 pounds of zinc. Company operations were severely curtailed by a chronic shortage of labor. The Mount Gaines Mining Co. worked the Mount Gaines mine on a restricted basis under a grant from the War Production Board and amalgamated 1152 tons of ore, from which bullion containing 1,612 ounces of gold and 487 ounces of silver and 67 tons of concentrates containing 1,089 ounces of gold and 356 ounces of silver were recovered.

Mother Lode district.—The Ruth-Bobby Mining Co. worked the Dry Creek lode from June 8 to December 31 and shipped 73 tons of ore containing 51 ounces of gold and 7 ounces of silver to a smelter. A small quantity of gold was recovered from a clean-up, by the Pacific Mining Co., at the Pine Tree and Josephine mines.

NEVADA COUNTY

Grass Valley-Nevada City district.—Under a grant by the War Production Board the Empire Star Mines Co., Ltd., resumed operations at the Empire Star group in March 1944 and operated until December 31. The grant limited employment by the company to 75 men, which curtailed production far below that of prewar years. The Idaho Maryland Mines Corp. was permitted to hire up to 200 miners under a War Production Board grant issued in March, but the company experienced difficulty in developing a working staff of this size. Most of the operations were carried on in the Brunswick section of the property.

ORANGE COUNTY

Santa Rosa district.—The Blue Light Silver Mines Co. worked the Silverado mine on a curtailed basis throughout 1944 owing to labor shortage; 666 tons of zinc ore containing 57 ounces of gold, 17,966 ounces of silver, 4,031 pounds of copper, 37,982 pounds of lead, and 38,419 pounds of zinc were shipped to a concentrator smelter.

PLACER COUNTY

Last Chance district.—The Red Star Mining Co., Inc., produced 69 ounces of gold and 6 ounces of silver during hydraulic test operations at the Red Star mine in 1944.

SACRAMENTO COUNTY

Folsom district.—Pacific Coast Aggregates, Inc., and the Fair Oak Gravel Co. produced 220 ounces of gold and 19 ounces of silver and byproducts during the preparation of gravel for concrete aggregates during 1944. The Natomas Co.—permitted to operate two units in its fleet of seven connected-bucket dredges—worked on this limited scale throughout the year. C. M. Craig produced gold as a byproduct of a gravel-washing plant.

SAN BERNARDINO COUNTY

Buckeye district.—Roosevelt Mines, Inc., shipped gold ore to a smelter from the Roosevelt mine.

Clark Mountain district.—L. D. Foreman & Co. shipped old slag from the Copper World smelter site for re-treatment during 1944. Dunton-Ray & Greenwood worked the Mohawk mine and shipped zinc-lead ore to a smelter.

Erchequer district.—The Dutch Oven Mining Co. worked the Von Trigger mine throughout 1944 and shipped copper ore to a smelter.

New York Mountains district.—The California Sulphur Co. produced lead-zinc ore at the Sagamore mine.

Randsburg district.—Hoeftling Bros. recovered placer gold as a byproduct of an operation carried on during 1944, principally for scheelite, at the Spud Patch mine. C. O. Mittendorf shipped silver ore to a smelter from the Coyote mine.

SAN JOAQUIN COUNTY

Camanche district.—The Gold Hill Dredging Co. was permitted to operate one dredge under special grant from the War Production Board during 1944 and elected to operate its Lower Comanche dredge. This electric dredge was equipped with 87 8½-cubic foot buckets.

SHASTA COUNTY

Flat Creek district.—The Mountain Copper Co., Ltd., mined zinc-copper ore from the Mattie ore body in the Hornet mine throughout 1944; 90,059 tons of ore were treated in the company 300-ton flotation mill, and 10,966 tons of copper concentrates (containing 413 ounces of gold, 74,138 ounces of silver, 2,557,500 pounds of copper, and 27,798 pounds of lead) and 2,767 tons of zinc concentrates (containing 51 ounces of gold, 11,012 ounces of silver, 50,497 pounds of copper, 11,340 pounds of lead, and 2,643,600 pounds of zinc) were recovered. Old flue dust from earlier smelting operations in the Shasta copper belt were recovered from the area where the recently completed Shasta Dam was causing a lake to form. Part of the material was shipped to a slag-fuming plant, principally for the recovery of zinc, and part was stored in an area beyond the prospective shore line of the growing lake.

French Gulch district.—The St. Jude Mining Co. worked the St. Jude mine and treated gold ore by amalgamation and concentration.

Redding district.—The Columbia Construction Co., Inc., recovered 491 ounces of gold and 52 ounces of silver as byproducts during the production of 582,158 tons of sand and gravel for use in the construction of Shasta Dam; with completion of Shasta Dam the operation

was suspended June 22, 1944, and the gravel-washing plant was dismantled.

SIERRA COUNTY

Allegany district.—The American Hill Mining Co. worked the American Hill and Pilgrim Annex mine during 1944 and treated gold ore by amalgamation. Original Sixteen to One Mine, Inc., carried on a limited operation throughout the year under a grant issued by the War Production Board. Gold ore was treated by amalgamation.

Downieville district.—C. L. Best produced a small quantity of gold from gravel mined at the Ruby drift mine. The Alpha Hardware & Supply Co. treated a small quantity of gold ore by amalgamation at the Brush Creek mine during the first 3 months of 1944. Later the property was leased to A. L. Merritt.

Pike (Slate Range) district.—W. C. Ennis worked the Bowman mine from June 5 to October 1 and recovered 60 ounces of gold and 7 ounces of silver by amalgamation of 180 tons of ore.

SISKIYOU COUNTY

Klamath River district.—The Gray Eagle Copper Co. operated the Eakin or Gray Eagle mine throughout 1944; 227,021 tons of copper ore treated in the company 700-ton flotation mill yielded 41,488 tons of concentrates (containing 3,188 ounces of gold, 14,264 ounces of silver, and 16,293,158 pounds of copper) which were shipped to a smelter. This operation produced 62 percent of the State output of copper in 1944.

Liberty district.—Judge Hydraulic Mine carried on hydraulicking at the Judge mine from January 1 to May 25. Alex Markon worked the Anna Johnson and Surprise quartz mines during the year.

Scott Bar district.—George A. Milne carried on hydraulicking at the Milne mine during 1944.

STANISLAUS COUNTY

La Grange district.—The Tuolumne Gold Dredging Corp. operated a connected-bucket dredge equipped with 100 12-cubic foot buckets throughout 1944 on a one-shift basis.

TRINITY COUNTY

Junction City district.—G. H. Bergin carried on hydraulicking from February 6, 1944, at the Canyon Placers mine. Chapman & Sons hydraulicked 20,000 cubic yards of gravel at the Chapman and Fisher mine and recovered 90 ounces of gold and 8 ounces of silver between March 1 and July 1. The Goldfield Consolidated Mines Co. worked the Red Hill mine by hydraulicking during 1944.

Weaverville district.—W. E. Woodbury conducted a hydraulic operation at the Rex mine.

TUOLUMNE COUNTY

East Belt district.—Edwin Harper worked intermittently at the Eureka pocket mine during 1944.

Mother Lode district.—In addition to the zinc-copper ore trucked from the Penn mine in Calaveras County, Miller & Clemson (Eagle

Shawmut Mine) treated gold ore produced at the Eagle Shawmut mine; 72,300 tons of gold ore treated by amalgamation and flotation yielded bullion (containing 388 ounces of gold and 105 ounces of silver) and 2,076 tons of concentrate (containing 5,194 ounces of gold, 2,712 ounces of silver, and 23,321 pounds of copper).

YUBA COUNTY

Camptonville district.—Experimental hydraulicking by H. M. Allen at the Joubert mine produced 47 ounces of gold and 3 ounces of silver from 7,900 cubic yards of gravel.

Yuba River district.—Yuba Consolidated Gold Fields was permitted to operate two of its fleet of six dredges from January 1 to December 31, 1944, under a War Production Board grant. The dredges in operation were both of Yuba type and used electric power; one had 126 and the other 135 18-cubic foot buckets.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN THE CENTRAL STATES

(MINE REPORT)

By A. J. MARTIN

SUMMARY

With most of the war projects for expanding mine production of copper, lead, and zinc in the Central States completed before the beginning of 1944, activity during the year centered chiefly on maintaining output from established operations. The labor shortage became acute in some districts after midyear, and the total production of each of these three metals was less in 1944 than in 1943. The decreases in copper and zinc were small and did not disturb war procurement agencies, as reserve stocks of both metals increased during the year; the decrease (7 percent) in lead, however, caused concern owing to the decline in stocks of that metal. In December the War Production Board restricted the use of lead for most civilian purposes and urged mine operators to take steps to increase production. The disseminated-lead district of Southeastern Missouri is the largest lead-producing district in the United States. The bulk of the district output comes from the large, well-developed, mechanized mines of the St. Joseph Lead Co. The rise in zinc consumption late in the year, which caused heavy withdrawals from slab zinc stocks, encouraged zinc-mine operators in their efforts to maintain production rates; also, the Surplus Property Disposal Act of 1944 removed some of the uncertainty that prevailed concerning the short-term outlook for the mining industry. Although ceiling market prices and general bonus-price levels previously set for copper, lead, and zinc were not changed in 1944, the bonus prices paid for the output of some of the individual mines varied as a result of quota adjustments, and the average over-all prices increased slightly. The Lake Superior district in Michigan produced 93 percent of the Central States output of copper, the Southeastern Missouri district 84 percent of the lead, and the Tri-State district (Kansas, Oklahoma, and Southwestern Missouri) 89 percent of the zinc and 14 percent of the lead. The Southeastern Missouri district also produced some copper and zinc. Other districts producing zinc and lead were Wisconsin-Northern Illinois (Upper

Mississippi Valley), Kentucky-Southern Illinois, and Central Missouri; Northern Arkansas produced some zinc.

The silver produced in the Central States is a minor byproduct derived from some of the base-metal ores. No mine production of gold was reported in the Central States from 1941 to 1944, inclusive.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063
1941.....	35.00	711+	.118	.057	.075
1942.....	35.00	711+	.121	.067	.093
1943.....	35.00	711+	.130	.075	.108
1944.....	35.00	711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of January 31, 1934. Treasury legal coinage value of gold from January 18, 1837, to January 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Co. for overquota production.

*\$0.71111111.

Mine production of gold, silver, copper, lead, and zinc in the Central States, 1940-44, in terms of recovered metals

¹ From placer prospecting.

Silver.—The output of recoverable silver from ores mined in the Central States in 1944 comprised 86,279 ounces derived from refining some of the lead bullion recovered from Southeastern Missouri lead ores, 54,218 ounces from Michigan copper ore, 5,964 ounces from Missouri lead-copper-cobalt-nickel-iron ore, and 2,437 ounces from Southern Illinois zinc-lead fluorspar and lead fluorspar ores.

Copper.—The bulk of the Central States output of copper comes from Michigan. Although a number of projects designed to augment production in Michigan were completed in 1943 and 1944, shortage of labor prevented full utilization of some of the productive capacity thus

obtained, and the State output was less than in 1943. Missouri production increased in 1944, as more copper was recovered as a by-product in smelting lead concentrates, and a substantial tonnage of copper concentrates was shipped from the new Madison mill, at Fredericktown, which treated lead-copper-cobalt-nickel-iron ore.

Lead.—The Central States produced 48 percent of the United States total mine output of lead in 1943 and about the same percentage in 1944. Production in Southeastern Missouri, which contributes most of the Central States output, decreased 5 percent from 1943; the output in the Tri-State district (Kansas, Southwestern Missouri, Oklahoma), also an important source of lead, decreased 19 percent. These two districts produced 98 percent of the Central States lead output in 1944; the rest came from Wisconsin, Illinois, Central Missouri, and Kentucky.

Zinc.—The 3-percent decrease in zinc production in the Central States in 1944 resulted largely from a 5-percent decline in output in the Tri-State district, which contributed 89 percent of the total in 1944 and 90 percent in 1943. A general review of mining and milling in this region is given in this chapter under Southwestern Missouri. The outputs in the Wisconsin-Northern Illinois and Kentucky-Southern Illinois districts were larger than in 1943. Other small zinc-producing districts in 1944 were Southeastern and Central Missouri and Northern Arkansas.

MINE PRODUCTION BY STATES AND REGIONS

Here production of silver, copper, lead, and zinc in the Central States in 1944, by States, in terms of recovered metals

State	Mines producing	Material sold or treated		Silver

¹ Only small-scale intermittent mining done in Arkansas from 1918 to 1944; Kentucky and Illinois excluded because part of the metal output (lead and zinc) was a byproduct of fluorspar mining, and the quantity of metal-bearing material hoisted could not be determined.² The percentages represent metal content of the ore insofar as it is recovered in the concentrates. In Michigan the metal so recovered is copper; in Missouri, copper, lead, and zinc; and in Kansas, Oklahoma, and Wisconsin, lead and zinc. The relative proportions of the metals are shown in the third table of this chapter and in tables of tenor of ore given in sections devoted to the respective States.**MINING AND METALLURGIC INDUSTRY**

As payments under the premium-price plan were liberalized to permit utilization of very low grade ores, the chief problem confronting the mining industry in its efforts to maintain production rates was shortage of manpower. In general, the principal producing mines were kept in operation throughout the year, their rate of output depending upon the number of workers obtainable. Some of the mines not already fully mechanized added more labor-saving machinery, and a number of small mines reported initial use of mechanical loading and haulage equipment underground. A few mines that were being prepared for operation in 1943, mostly as war projects, began pro-

doing in 1944, but otherwise there was little expansion in mining activity. The Bureau of Mines, in cooperation with the Geological Survey, continued its investigation of sources of strategic and critical minerals; the work done on copper, lead, and zinc included exploratory drilling, geophysical surveys, scattered field examinations, and metallurgical tests on certain types of ores. Flotation was used in conjunction with gravity concentration in nearly all the mills, and flotation concentrates comprised 32 percent of the total copper concentrates (excluding copper-lead flotation concentrates from Missouri), 43 percent of the lead concentrates, and 60 percent of the zinc concentrates produced. The location of the smelters that treat the concentrates is given in the 1943 report of this series (Minerals Yearbook, 1943). The installation of waelz plants at some zinc smelters in recent years has resulted in recovery of additional metal from ores mined in the past and in reducing over-all current smelting losses. Old residues, current residues, and a small tonnage of crude carbonate ore treated in 6 waelz plants in the Central States in 1944 totaled 204,551 tons yielding 33,333 tons of oxide averaging 66 percent zinc and about 3 percent lead. Most of the oxide was smelted along with concentrates to produce metal.

REVIEW BY STATES

ARKANSAS

Production of zinc concentrates in Arkansas in 1944 totaled 57 tons of carbonate, compared with 235 tons of combined carbonate and sulfide in 1943. No lead was produced in the State in 1944 and only 1 ton in 1943. The Big Hurricane zinc carbonate open-pit mine in Searcy County was reopened in 1944 by the Grimmett Construction Co. Preliminary work included removal of overburden and building a 500-ton mill. The mill made several runs late in the year and produced a car of concentrates. The Gloria-Jack Pot (Moark) mill at Zinc in Boone County was reconditioned and treated about 200 tons of ore during test runs. The Advance Mining Co. erected a dry-concentration mill at the North Star mine near Harrison and made experimental runs on zinc sulfide ore. From November 1943 to May 1944 the Bureau of Mines did exploratory drilling totaling 2,729 feet on the Moark, Coon Hollow, Big Hurricane, and Spier properties.

ILLINOIS

Northern Illinois (see section on Wisconsin for output data).—The Ginte Mining Co. operated the Graham-Ginte mine and 400-ton jig mill north of Galena throughout 1944; the product, rougher jig concentrates, was sold to the Vinegar Hill mill at Cuba City, Wis. The Gray property south of Galena was acquired under lease by Tri-State Zinc, Inc., which from June through October sank a 197-foot shaft, cut stations, drove drifts into the ore, and built a 600-ton flotation mill. Mining and milling began in November. Exploratory drilling on the property was undertaken by the Bureau of Mines early in 1943, and, as a result of favorable showings and to encourage development of the property, drilling was continued to July 1944. The ore body was found to extend into the adjoining Bautsch property,

which was also drilled during 1944. Other Illinois properties drilled were the Lonergan at Menominee, the Skene at Elizabeth, and the Boevers near Galena.

Southern Illinois.—The Mahoning Mining Co. zinc-lead-fluorspar mines near Cave in Rock, Hardin County, continued to produce most of the output of zinc and lead from Southern Illinois. In 1944 the company operated the W. L. Davis-Deardorff, Anna L. Davis, East Green, and West Green shafts, which are 311, 165, 230, and 363 feet deep, respectively. The ore from all four shafts was trucked to the company flotation mill at Rosiclare for treatment. The products of the mill were fluorspar concentrates (mostly acid grade), zinc concentrates containing 62.60 percent zinc, and lead concentrates containing 69.76 percent lead. Besides ore from company mines, the mill treated some custom ore and bulk concentrates containing zinc, lead, and fluorspar, mostly from the Rosiclare Lead & Fluorspar Co. and Aluminum Ore Co. mines. Hillside Fluor Spar Mines and the Alco Lead Co. shipped byproduct lead concentrates. The Minerva Oil Co. newly developed zinc-fluorspar mine northeast of the Mahoning mines began producing in March 1944. The mine is equipped with a 200-ton flotation mill producing fluorspar concentrates and zinc concentrates; the zinc concentrates shipped averaged 62.37 percent zinc. The mine is opened by a 645-foot double-compartment shaft and drifts on the 640-foot level. The total output of lead concentrates in Southern Illinois in 1944 was 2,753 tons averaging 69.60 percent lead and about 7 ounces of silver to the ton, and that of zinc concentrates was 9,891 tons averaging 62.56 percent zinc. Production (in terms of recoverable metals) amounted to 1,878 tons of lead, 2,437 ounces of silver, and 5,569 tons of zinc, compared with 1,959 tons of lead, 2,153 ounces of silver, and 4,699 tons of zinc in 1943.

KANSAS

The Kansas zinc and lead mines are in the Tri-State (Joplin) mining region, embracing parts of Cherokee County, Kans., and Ottawa County, Okla., and about 12 counties in Southwestern Missouri. General details of the Tri-State mining industry are given in the following pages on Southwestern Missouri.

Production of zinc concentrates in Kansas increased 12 percent in 1944 from 1943, and lead concentrates decreased 1 percent. The Baxter Springs-Blue Mound-Treese area produced 104,750 tons of zinc concentrates and 11,511 tons of lead concentrates (89 and 95 percent, respectively, of the State total) in 1944. About 35 percent of the crude ore mined in the area was concentrated in the Central mill of the Eagle-Picher Mining & Smelting Co. at Cardin, Okla. Most of the ore was transported to the mill over the Northeast Oklahoma Railroad, which has spur tracks from the main line to the principal ore-hoisting shafts. Eagle-Picher mines in Kansas shipping to the mill were the Big John, Leopard, Parmenter, Sim C., Webber mines, Westside mines, Wilbur, and Youse-Slaughter. The Paxson, Stoskopf, and Swalley "D" mines and the Paxson mill were operated by Eagle-Picher as agent for the Metals Reserve Company.

Mine shipments of lead and zinc in Kansas, 1940-44

¹ In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the value of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

Factor of lead and zinc ore and old tailings milled and concentrates produced in Kansas, 1943-44

¹ Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates; data on tailing losses not available.

The St. Louis Smelting & Refining Co. mines served by the company Ballard central mill were large producers; they comprised the Ballard, Bailey, Clark, English "O", Keith, Shanks, Slaughter, Walter H., and Moore mines. The No. 4 mine in Oklahoma also shipped ore to the Ballard mill in December. The Smith and Swalley (Beck) mines and the MacArthur mine shipped ore to the Beck No. 3 mill at Baxter Springs. The Liza Jane (Lula Bell) shipped to the Farmington mill in Oklahoma. The Harris Mining Co. Robinson, Silver Fox, and Evans Wallower No. 24 mines, the Federal Muncie-Tar Creek-Semple group, and the Southern and Jarrett mines shipped to the Youngman mill. The Bilharz Mining Co. operated its mill and three shafts on the Bilharz-Brewster property. The Bendelari, Ebenstein (Bilwil), Guaranty No. 2 (Robob), Mark Twain (old Blue Mound), and Wright mines shipped ore to the Central mill, and the M. & H. (Lawrence-McNulty) shipped to the Mission mill (Okla.). The Dines Mining Co. operated the Hartley mine in Kansas and the Dines No. 3 in Oklahoma; the ore produced was treated in the company mill in Kansas, which also treated custom ore from the C. K. & E. (Stebbins)

and Robinson (Jarrett) mines. The Peru mine and mill, operated since October 12, 1940, by the Madison Mining Co., were closed in November 1944. The Wade mill handled company ore from the Wade-Hunter mine and custom ores from other small mines in Kansas and Oklahoma. The Worley (New Blue Mound) mill treated old tailings from Kansas and custom mine dirt from Oklahoma. The Barr Cleanup Co. ran a section of the old Webber mill on clean-up material. The Captain and Semple (Early Bird) tailing mills were run throughout 1944.

At Galena, the Eagle-Picher Illinois and Murphy mines and the Galena Mining Co. Southside mine shipped ore to the Central mill. The Mess Cave Mining Co. worked the Mess Cave-Windsor by open-pit methods, shipping the ore to custom mills. Tri-State Zinc, Inc., built a tailing mill on Short Creek and operated it from April to November. Other small-scale operators at Galena shipped considerable ore to custom mills. At Peacock, the Carson Mining & Milling Co. operated its tailing mill throughout the year. At Lawton, the Eastern Mining Co. shipped some ore from the Fletcher mine.

In the Kansas part of the Waco district, the St. Louis Smelting & Refining Co. operated the Acme, Barnsdall No. 1, and Grasselli mines and the Waco No. 9 mill. F. W. Evans Mines operated the Barnsdall No. 3 and O'Neill mines and the F. W. Evans mill. Both mills also handled company ore from other mines across the Stateline in Missouri. The Stotts City Mining Co. operated the J. M. and Oscar Bennett mines, shipping the ore to the No. 9 mill.

KENTUCKY

Mines in Kentucky, including fluorspar mines yielding zinc and lead as byproducts, produced 341 tons of recoverable zinc and 170 tons of lead in 1944, compared with 931 and 240 tons, respectively, in 1943. The Eagle-Picher Nunn zinc-lead mine near Marion, principal producer of zinc in 1943, was idle throughout 1944. The Twin Valley Mining Co. operated the old Gratz zinc-lead mine and 100-ton mill in Owen County on a small scale from January to November. In Livingston County, the Kentucky Fluor Spar Co. shipped byproduct lead concentrates to the Federal smelter at Alton, Ill., and the Eagle Fluor Spar Co. shipped zinc-lead ore to the Eagle-Picher Central mill at Cardin, Okla. In Crittenden County the United States Coal & Coke Co. shipped byproduct zinc and lead concentrates, and the National Fluorspar Co. shipped byproduct lead concentrates. The Corod Minerals Corporation 150-ton custom flotation mill at Marion, built to treat zinc- and lead-bearing fluorspar, operated a few weeks early in 1944; the output included no lead concentrates and less than a car of zinc concentrates. Some ore containing zinc, lead, and fluorspar was shipped from Kentucky mines to the Mahoning mill at Rosiclare, Ill.

MICHIGAN

Production of copper from mine rock in Michigan increased 1 percent in 1944 from 1943 but that from reclamation plants decreased 31 percent—a 9-percent drop in the State total. The sharp decline in

Output from old tailings had been anticipated, as the reserves of high-grade conglomerate tailings (an important source of copper during the past 30 years) were nearly exhausted by the end of 1943, and most of the remaining sands that could be reclaimed were low-grade argillaceous tailings. The anticipated larger increase in production from mine rock did not materialize owing to shortage of labor in the mines. The ceiling price of copper remained at 12 cents a pound throughout the year, and the Government continued to pay special or premium prices to individual mines. The average value per pound of the copper reported by the mine operators (including increment from special prices and premiums for overquota production) was 14 cents, compared with 16.19 cents in 1943 and 12.83 cents in 1942. The rock treated in 1944 totaled 2,382,525 tons and reclaimed tailings 3,027,713 tons, compared with 2,311,669 and 2,091,925 tons, respectively, in 1943. The tailings yielding 25 percent of the copper in 1944 and 32 percent in 1943.

The concentrate ("mineral") produced at mills in Michigan in 1944 and the mass copper shipped direct from the mines were smelted at plants of the Calumet and Hecla Consolidated Copper Co. at Hubbell and the Copper Range Co at Houghton. Some of the copper bullion was cast into anodes and shipped to the electrolytic refinery at Laurel, N. Y., where silver was recovered. Some native silver was recovered in mill jigs and by hand-picking from tables; that alloyed with copper was treated by ammonia leaching to remove the copper before shipment to the mint. Considerable silver not reported as such production is retained in copper bullion used for making commutators in electric-motor armatures, engravers' plate, trolley wire, and other articles. The quantity of silver in this bullion ranges from 15 to 26 ounces to the ton. Of this quantity, about 10 ounces is derived directly from the ore and the rest is purchased from dealers and added to the bullion. Bullion containing the added silver brings a premium of one-half cent a pound. The silver is said to raise annealing temperatures, prevent brittleness, facilitate soldering, and increase hardness and conductivity.

Mine production of silver and copper in Michigan, 1940-44¹

Year	Silver (fine ounces)	Copper			Concentrate ("mineral")		Crude ore and sands (short tons)
		Pounds	Yield		Pounds	Yield (percent copper)	
			Pounds per ton of crude ore and sands	Percent			
1940	88,657	90,396,000	20.4	1.02	138,451,495	65.3	4,438,219
1941	60,796	92,880,000	21.7	1.08	141,100,268	65.8	4,282,448
1942	61,674	91,358,000	20.9	1.05	141,372,582	64.6	4,362,640

¹Figures based upon actual recovery of copper from "mineral" smelted and estimated recovery from "crude" not smelted during year.

Value of silver and copper produced in Michigan mines, 1940-44

Year	Silver	Copper		Total	Year	Silver	Copper		Total
		Total	Per ton of crude ore and sands				Total	Per ton of crude ore and sands	
1940....	\$63,045	\$10,214,748	\$2.30	\$10,277,793	1943....	\$34,474	\$12,188,640	\$2.76	\$12,193,114
1941....	43,233	10,959,840	2.56	11,003,073	1944....	38,555	11,453,670	2.12	11,492,225
1942....	43,857	11,054,318	2.53	11,098,175					

¹ Value of copper calculated at average weighted price (including Government bonuses) for all domestic copper sold (see first table of this chapter, footnote 3). If calculated at actual prices paid to Michigan operators, the value of the copper was—1942: \$11,722,792, or \$2.69 to the ton of crude ore and sands; 1943: \$15,139,831, or \$3.44 to the ton; 1944: \$14,033,131, or \$2.59 to the ton.

The Calumet and Hecla Consolidated Copper Co. operated the Ahmeek stamp mill, the Lake Linden and Tamarack reclamation plants, the Hubbell smelter, and the Ahmeek, Central, Douglass, Iroquois, North Kearsarge, Peninsula, Allouez No. 3, and Centennial mines. All the mines except the last two were also in operation in 1943; the Allouez No. 3 was reopened in January 1944 and the Centennial in March. Reconditioning of the idle Calumet mill, begun in 1943 to provide additional milling capacity, was suspended owing to an acute labor shortage that prevented expansion of crude ore output to the level contemplated. The following data are extracted from the annual company report to stockholders:

Because of a gradually increasing shortage of labor, underground production fell off materially during the latter part of the year. This factor, coupled with a declining grade of ore and advancing supply and labor costs, resulted in a general increase in operating expense. During 1944 the company purchased two large areas of land and other smaller ones on the copper formation in Michigan. One area embraced the old Mass-Michigan and Flint Steel properties in Ontonagon County, where previous exploration under an option to purchase had indicated the presence of a body of low-grade ore; the purchase price was \$40,000. Another area purchased comprised the Keweenaw Copper Co. property in Keweenaw County adjacent to lands already owned by Calumet and Hecla. The lands and rights in lands aggregate approximately 35,544 acres, all in the known mineral belt. Payment for the lands and other assets acquired was made by issuance to the Keweenaw Copper Co. of 62,768 shares of the authorized but unissued capital stock of Calumet and Hecla. A smaller area acquired included the lands of the old Torch Lake Mining Co. just south of Calumet, purchased for \$10,000. The Ahmeek mill stamped the rock from all operating mines and explorations, amounting to 1,494,417 tons. The Lake Linden reclamation plant operated on conglomerate tailings from May to November and on adjacent amygdaloid sands the rest of the year. At the Tamarack reclamation plant the conglomerate tailings deposit was depleted in August. Production up to that time had totaled 97,894,087 pounds of copper. With the exhaustion of the conglomerate deposit the leaching process was discontinued, and the regrinding and flotation equipment was remodeled for more efficient treatment of the marginal-grade amygdaloid tailings. Reconstruction of the discontinued leaching-plant machinery is now in progress to adapt it to the production of copper oxide from secondary copper products.

The Copper Range Co. operated the Champion and Globe mines, Freda mill, and Houghton smelter throughout 1944 and the reclamation plant at the Freda mill about 6 months. The smelter treated company concentrates as well as custom concentrates and mass copper from the Isle Royale and Quincy mines. Data extracted from the annual company report to stockholders follow. Production from the two mines totaled 13,989,318 pounds of refined copper,

compared with 16,886,013 pounds in 1943. The decrease in production was due mainly to loss of men to the armed forces and to the drop in average grade of ore mined. The reclamation plant produced 554,909 pounds of refined copper, compared with 571,674 pounds in 1943. Exploration was carried on at a somewhat lower rate than in 1943 and was confined principally to lodes east and west of the main lode, which appears near exhaustion. Development of the explored areas proceeded at an increased rate and resulted in a substantial increase in ore reserves. Diamond drilling at the White Pine property was continued. The results of this work and other studies have been sufficiently favorable to warrant further and more detailed tests and investigations toward formulating plans for development.

The Isle Royale Copper Co. operated the Isle Royale mine and mill throughout 1944. Ore treated totaled 311,072 tons yielding 1,795,176 pounds of fine copper, compared with 308,446 tons yielding 6,279,771 pounds in 1943. According to the annual company report to stockholders, operations were carried on under adverse conditions. The most serious set-back was the loss to the armed forces of virtually all employees in the 19 to 25 age group. A further increase in the rate of absenteeism, especially among underground workers, made it necessary to concentrate on production and curtail exploratory work. Only two stamp heads were operated in the mill, and for the most part milling was on the basis of five days a week. Attention was paid to the problem of reworking accumulated stamp sands. Some experimental work was done during the year, but the results were inconclusive; additional work will be done in 1945.

The Quincy Mining Co. ran its Quincy mine and mill and new 4,000-ton tailings reclamation plant throughout 1944. Output from the mine increased slightly over 1943. The reclamation plant, which began operating on Torch Lake November 1, 1943, performed well within original estimates as to sand-treatment capacity, efficiency in copper recovery, and quantity of copper produced.

MISSOURI

In 1944 Missouri again maintained, by a wide margin, the rank it has held for 37 years as the chief lead-producing State; it ranked ninth in zinc production. Silver and copper continued to be recovered as byproducts in smelting lead concentrates from Southeastern Missouri, and considerable copper and a little silver were derived from lead-copper-cobalt-nickel-iron ore. Silver recovered totaled 92,243 ounces and copper 3,302 short tons, compared with 111,285 ounces and 1,340 tons, respectively, in 1943. In the sale of the lead concentrates, no value is attached to the silver and copper, as the quantity recovered per ton of concentrates is very small. The lead output of the State comes largely from the Southeastern region and the zinc mostly from Southwestern Missouri. The Central district of Missouri produced some lead and zinc annually from 1940 to 1944, inclusive; the figures are included with those of Southeastern Missouri in the table that follows.

Mine production of lead and zinc in Southeastern and Central Missouri, 1940-44

Year	Lead concentrates (galena)		Zinc concentrates ¹		Metal content ²			
	Short tons	Value ³	Short tons	Value	Lead		Zinc	
					Short tons	Value	Short tons	Value
1940.....	232, 871	\$14, 269, 600	815	\$20, 000	169, 908	\$16, 990, 800	233	\$29, 358
1941.....	228, 572	15, 404, 226	5, 192	73, 202	164, 388	18, 740, 232	1, 100	165, 000

¹ Includes zinc-lead carbonate concentrates.

² In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

³ Values given are to a certain extent arbitrary, as part of the lead concentrates are smelted by the producer.

• Includes 450 tons recovered from lead-smelter slags.

• Includes 360 tons recovered from lead-smelter slags.

• Includes 776 tons recovered from lead-smelter slags and byproduct matte from lead smelting.

Southeastern and Central Missouri.—Production of recoverable lead in Southeastern Missouri was 169,622 tons in 1944, compared with 179,012 tons in 1943.

The mines of the St. Joseph Lead Co. in St. Francois County continued to contribute the bulk of the output. The groups operated in 1944 were the Bonne Terre, with 3 operating shafts; Desloge, 2 shafts; Federal, 7 shafts; and Leadwood, 1 shaft. The depth of the shafts ranged from 181 to 755 feet and averaged 424 feet. Each group has a central ore-hoisting shaft and a mill; the other shafts are used for men, supplies, and poor rock. The mills together have a total daily capacity of 21,400 tons. Mining operations were hampered by withdrawal of men for military service and for other war industries. Many of the men had been trained under the company system of employing local young men and training them for key jobs, and their departure caused a serious loss in over-all labor efficiency. The continued high rate of ore extraction required much exploration and development to maintain ore reserves. Diamond drilling at the four groups of mines totaled 3,408,574 feet in 1944 and drifting and raising 68,823 feet. According to the company annual report to stockholders, development in 1944 was most satisfactory in proving additional ore reserves. At the request of Government war agencies, late in the year the company curtailed development and continued to operate its mines beyond their economic limits to help alleviate the lead shortage. Some of the concentrates from the mills were shipped to the company Herculeanum smelter and some to the Federal smelter at Alton, Ill. The concentrates contain a little silver, copper, and zinc, part of which was recovered in smelter byproducts. Additional zinc was recovered as metal from slag treated in the electrothermic zinc plant at the Herculeanum smelter.

In Madison County the Mine La Motte mine and 1,500-ton mill of the Mine La Motte Corporation (50-percent owned by the St. Joseph Lead Co.) were run continuously. Development during the

year totaled 4,192 feet of drifts and raises and 60,636 feet of churn drilling. The Fredericktown Lead Co. operated its 400-ton mill and the Catherine and Fleming mines. Part of the ore mined came from the new 73-foot shaft sunk in 1944 on a previously undeveloped part of the Catherine property. In January the Park City Consolidated Mines Co. began shipping lead concentrates from its 500-ton flotation mill at the company newly developed Ruth mine; the mine and mill were operated throughout 1944. The mine is opened by a 370-foot shaft and about 1,625 feet of drifts. At the Madison mine group of the St. Louis Smelting & Refining Co. (comprising the leased Missouri Cobalt property and other company-owned properties) preliminary development was completed early in 1944, and the newly installed 600-ton flotation mill began operating in February. The mine is worked through 3 shafts averaging about 425 feet in depth. The ore contains lead, copper, cobalt, nickel, and iron; the products of the mill were copper-lead, lead-copper, cobalt-nickel, and iron concentrates. The copper-lead concentrates were shipped to smelters at Garfield, Utah, and El Paso, Tex. The lead-copper concentrates were shipped to the Herculaneum (Mo.) smelter, and the iron concentrates were discharged to pond storage. At first the cobalt-nickel concentrates were treated in a reverberatory furnace and roaster adjacent to the mill and then shipped to the Ferro Enamel Corporation, Cleveland, Ohio, for final treatment; later, preliminary treatment involved roasting only. Of the 242,829 tons of lead concentrates made in 1944 in Southeastern Missouri, about 112,469 tons were flotation concentrates.

At Valles Mines, Jefferson County, the DeSoto Lead & Zinc Co. 200-ton mill operated on zinc-lead-iron carbonate ore from dumps on the Valle Mining Co. properties; the concentrates were shipped to the Ozark pigment plant at Coffeyville, Kans. About 135 tons of galena were shipped from barite workings in Southeastern Missouri.

In Central Missouri the Wemhaner Mining Corporation mined zinc, lead, and coal from the open-pit mine on the Monarch Coal & Mineral Co. land in Moniteau County. The ore was treated in a 100-ton jig mill. The D. F. & H. Mining Co. operated the Lowery lead-barite open-pit mine and 100-ton mill near Enon from January to August, when the deposit was reported worked out.

Southwestern Missouri.—The following table, the first five paragraphs, and the graphs under this heading pertain to the Tri-State mining industry as a whole; the remaining text reviews mining and milling in Southwestern Missouri only.

The monthly output rate for Tri-State zinc concentrates derived from crude ore in 1944 trended sharply downward after June and averaged only 20,870 tons in the last quarter of the year, compared with 29,568 tons in the first quarter; the rate for concentrates from old tailings remained fairly constant from January to November but dropped in December. About 52 mills were operating in the region in December 1944, of which 16 were tailing mills, compared with 58 in December 1943, including 17 tailing mills. Stocks of concentrates in the mill bins were small at the end of 1944; the zinc concentrates accumulated in the first part of the year at the Paxson mill—a Metals Reserve Company project—were shipped to the Henryetta (Okla.) smelter.

Production of lead and zinc concentrates in the Tri-State district (Kansas, Oklahoma, and Southwestern Missouri), 1940-44

FROM CRUDE ORE

Year	Ore, etc., milled (short tons)	Concentrates pro- duced (short tons)		Concentrate recovery (percent)		Average assay of concentrates (percent)		Average value per ton of concentrates

The method of marketing the mine output of the Tri-State or Joplin region is explained in the reports of this series for 1940 and 1941. The total value given for all the concentrates is based upon actual receipts by the sellers, including premiums paid by the Government since February 1, 1942, for overquota mine production. The quoted weekly market price for zinc concentrates at Joplin remained at \$55.28 a ton throughout 1944; the quoted metal contract price on galena continued at \$76.54 until March 18, when it dropped slightly to \$76.01, and it remained at that level the rest of the year. Government premium payments for 60-percent zinc concentrates continued at \$29.70 a ton for assigned production under the A-level quota, \$59.40 for B-level, and \$89.10 for C-level; for 80-percent lead concentrates the payments were \$41.80 for A-level and \$83.60 for B-level.

The B- and C-level premiums enabled many marginal and sub-marginal mines to operate throughout 1944, but in general neither these mines nor the higher-grade mines could maintain capacity output owing to shortage of labor and difficulty in obtaining some materials, especially heavy-duty tires for ore trucks. Keeping the low-grade mines open is an important factor in the operation of some of the higher-grade mines in areas such as the Picher field, where underground workings of many mines are connected and pumping costs are too high to be borne by a few mines. Also, low-grade ore can be treated economically by utilizing excess capacity of active mills. Mechanized mining offers interesting possibilities for extending the productive life of the district. Mechanized open-pit mining at Oronogo, Webb City, and Galena has proved feasible for working certain types of deposits, and another large-scale open-pit operation near Baxter Springs was undertaken by F. W. Evans Mines early in 1945.

FIGURE 1.—Average prices received by sellers per ton of concentrates in the Tri-State district, 1907-44.

FIGURE 2.—Quantity of crude ore milled in the Tri-State district, 1907-44.

FIGURE 3.—Metal recovered per ton of crude ore (rock) milled in the Tri-State district, 1907-44.

Activity in prospect drilling decreased somewhat from 1943. Work was completed in January 1944 on the exploratory project of Brown & Root as agent for the Metals Reserve Company in the Webb City field, where 45,300 feet of churn drilling proved the existence of large low-grade deposits, which if needed could be utilized for war production at premium prices. The Bureau of Mines did churn drilling in the Stotts City, Wentworth, Joplin, Galena, Baxter Springs, Ozark, and Melrose areas and made scattered field examinations. The Reconstruction Finance Corporation continued its mine-loan office at Joplin.

In Southwestern Missouri production of zinc concentrates increased 17 percent in 1944 over 1943 and that of lead concentrates decreased 18 percent. The Oronogo Circle open-pit mine of the Oronogo Mutual Mining Co. was again the largest individual producer of zinc concentrates in Missouri. Part of the ore was treated in the Eagle-Picher American mill on the property, and part was shipped to the Eagle-Picher Central and Bird Dog mills in Oklahoma. The pit is 230 feet deep. Ore from a shaft on the property operated by Fenix & Sons was shipped to the Central mill. Other large Missouri producers were Kansas Explorations, Inc., operating the Snapp and Buckingham-Gibson mines and the Snapp mill near Oronogo and the Jasper mine and mill near Joplin; the Federal Mining & Smelting Co., operating the Granby-American and Davis groups of mines, the Granby-American mill, and the Duenweg mine and mill; the American Zinc, Lead & Smelting Co., operating the Hunter mine and mill at Aurora throughout the year and the Henckel and Smith mines near Duenweg from January 1 to October 6; the St. Louis Smelting & Refining Co. Waco mines and the F. W. Evans Waco and Smithfield mines (ore treated in company mills in Kansas); Cooley Bros., operating the Sucker Flat open-pit mine and washing-concentrating plant at Webb City (closed

in July); and the Missouri Mining Co. tailing mill at Chitwood. The Eagle-Picher Navy Bean mill near Wentworth and the mines served by it were closed in January 1944.

Other producing mines equipped with mills were the Fenix & Martin La Tosca at Oronogo, the Capital at Stotts City, the Northside near Joplin, and the Playter (Reynolds group) at Waco. The Playter mill also treated custom ores, mostly from the Anderson (K. C. B.) property near Carl Junction, the Pleasant Valley-Southside near Carthage, the Lucky Tiger at Neck City, and the Little Pat in Joplin. The St. Louis Mining & Milling Co. custom mill at Thoms Station treated ore from the Pearl, Big Tom, and Coble mines near Thoms Station; the Richey-Thomas at Smithfield; the O'Jack near Joplin; the Sucker Flat (Cooley Bros.) at Webb City; and other small producers. Part of the ore from the O'Jack was milled at the Southside mill (operated by the C. & O. Mining Co. after September), and part of that from the Richey-Thomas was milled in the Lucky Jack mill near Carl Junction. The Wentworth Mining & Milling Co. ran the Kline mine and mill at Wentworth from May to September. The Sciota mill at Webb City treated coarse rock reject from the Cooley plant during January and February and tailings from the Gaunt Mining & Milling Co. lease during August, September, and October. Small tailing mills at Webb City, Neck City, and Granby produced some concentrates. The Monark mine at Ozark made a small output early in the year but was idle after May 9.

Most of the carbonate shipped from Southwestern Missouri in 1944 came from the Southwest Mining Co. mine at Stark City, equipped with a 250-ton mill. Some of the concentrates were shipped to the Athletic smelter at Fort Smith, Ark., and some to the E. I. du Pont de Nemours smelter at Meadowbrook, W. Va. Three cars of carbonate were shipped from Granby to the smelter at Meadowbrook, and 22 cars of low-grade carbonate were shipped from the Alice mine near West Plains to a waelz plant at La Salle, Ill.

OKLAHOMA

Mining and milling in the Tri-State region—which includes Northeastern Oklahoma—are discussed in the preceding pages on Southwestern Missouri. The Oklahoma area produced 48 percent of the total Tri-State output of zinc and 50 percent of the lead in 1944, compared with 57 percent of both zinc and lead in 1943. Production of recoverable zinc decreased 20 percent from 1943 and lead 29 percent. From 1918, when the Oklahoma output first surpassed that of Missouri, through 1944 Oklahoma produced 65 percent of the district total output of concentrates, and the crude ore extracted averaged 5,020,669 tons annually. This heavy drain upon ore reserves, with little recent expansion of the productive area, is reflected in the declining output of the past three years; however, the maximum potential output possible under prevailing prices (including the Government bonus) was not attained owing to labor shortage.

Mine shipments of lead and zinc in Oklahoma, 1940-44

Year	Lead concentrates (galena)		Zinc concentrates (sphalerite)		Metal content ¹			
	Short tons	Value	Short tons	Value	Lead		Zinc	
					Short tons	Value	Short tons	Value
1940	27,913	\$1,656,497	300,984	\$12,672,186	21,240	\$2,124,000	162,935	\$20,529,810
1941	32,628	2,202,876	307,207	15,427,235	25,021	2,852,394	166,602	24,990,300
1942	29,794	2,985,285	272,209	19,163,622	22,806	3,056,004	146,510	27,250,860
1943	26,423	3,208,885	213,195	21,251,796	19,733	2,959,950	114,085	24,642,360
1944	18,455	2,258,188	170,470	18,067,967	13,944	2,231,040	91,449	20,850,372

¹ Calculating metal content of the ores from assays allowance has been made for smelting losses of both metal and base. In comparing the values of ore and metal it should be borne in mind that the value given for ore is that actually received by the producer, whereas the value of the lead and zinc is calculated at the average price for all grades.

² Includes 38 tons of zinc carbonate averaging 31.03 percent zinc.

Tonnage of lead and zinc ore, old tailings, and slimes milled and concentrates produced in Oklahoma, 1943-44

¹ Includes 58 tons of carbonate averaging 31.03 percent zinc.

² Figures represent metal content of the crude ore (or "dirt") only insofar as it is recovered in the concentrates, data on tailing losses not available.

The Central mill of the Eagle-Picher Mining & Smelting Co. at Cardin is the largest zinc-lead ore-reduction plant in the United States; it has a capacity of over 14,000 tons daily and is equipped with differential-density (sink-and-float) preliminary-concentration units, which furnish an enriched product for treatment by jigging and flotation. Improvements made in the mill in 1944 included equipment for using magnetic ferrosilicon to replace galena to maintain the high density of the heavy medium in the preliminary concentration units, and a gas-fired drying unit for lowering the moisture content of the zinc flotation concentrates. Crude ore treated during the year totaled 3,433,670 tons, of which 2,213,214 tons (64 percent) came from Oklahoma mines, compared with 3,762,266 tons in 1943, of which 2,662,101 tons (71 percent) came from Oklahoma. Eagle-Picher mines in Oklahoma shipping to the mill were: Blue Goose mines, Buffalo, Crystal-Central, Goodeagle mines, Gordon No. 2, Grace Walker mines, Hum-bah-wat-tah mines, John Beaver No. 2, Little Greenback, Mehunka, Netta, See Sah, Slim Jim-Vantage, Stanley, and Wesah

Greenback; other large Oklahoma shippers to the mill were: Davis Big Chief Mining Co. (Skelton, Imbeau, Lucky Bill), Federal Mining & Smelting Co. (Lucky Syndicate-Howe, Lucky Bill, Gordon), M. & M. Mining Co. (Crawfish, Piokee, La Salle, White, Swift), F. W. Evans (Shorthorn, Craig), Mahutska Mining Co. (Acme-Blackhawk, Cortez-Childress), Carpenter Mining Co. (New York, Oko), Bluebird Mining Co., and W. M. & W. Mining Co. (Velie). The Eagle-Picher 2,400-ton Bird Dog mill operated from January to May on ore from the Oronogo Circle mine in Missouri and company mines at Galena, Kans.

Other large producing mines equipped with mills were: Evans-Wallower No. 7, Scott (Jane E.), Kansas Explorations (Ritz), Lawyers Lead & Zinc Co. (mine rock and old tailings), Lula Bell (Farmington), Rialto Mining Corporation, Weidman Mining Co. (Woodchuck, Townsite), and United Zinc Smelting Corporation (Royal group). The Royal mill also handled custom ore from the Dixie R. mine and company ore from the newly developed Park Walton mine 8 miles west of Picher. Development at the Park Walton during the year included a second shaft 349 feet deep and 475 feet of drifts. Work on constructing a mill began in January 1945. The M. & W. Mining Co. Brewster-Huttig and Ninety-Six mines and the Dobson No. 4 and Pelican shipped ore to the Beck No. 1 mill. Cameron & Henderson operated the Romo mill on ore from company mines and custom ore from the Craig (Keeton) lease. The Mission mill handled some of the ore from the Craig lease and other custom ore, mostly from the Graham-Houston, Lotson, and Montreal mines. The St. Louis No. 4 mill treated crude ore and old tailings from the No. 4 property. The Baird, Mary C., and Ravelin (Skelton property) mines shipped ore to the Worley mill in Kansas, and the Dines No. 3 shipped to the Dines mill, also in Kansas.

All the large Oklahoma tailing mills that were active in 1943 continued running throughout 1944; they comprised the Atlas, Big Chief, Britt & Britt, C. G. & C., Cardin Nos. 2 and 3, Evans-Wallower No. 4 (tailings and some mine rock), Semple (Martin), Tri-State Zinc Ottawa and Sooner, and Western. The DeMier-Smith mill at Commerce was operated a short time in 1944 but was destroyed by fire September 4.

The Davis zinc district, Murray County, from which a little ore was shipped in 1943, produced none in 1944.

WISCONSIN

The Wisconsin zinc and lead district is in the Upper Mississippi Valley region, embracing parts of Grant, Iowa, and Lafayette Counties, Wis., Joe Daviess County, Ill., and Clayton and Dubuque Counties, Iowa. The Iowa part has had no output since 1917, and the only activity reported there in 1944 was exploratory drilling on two properties by the Bureau of Mines. In Wisconsin and Illinois, activity was stimulated by the war demand for metals and Government premium prices paid for overquota production. In 1944 the total output of finished (60-percent) zinc concentrates was 31,819 tons and lead concentrates 2,085 tons, compared with 28,768 and 1,430 tons, respectively, in 1943. The principal producer of finished concentrates was the Vinegar Hill Zinc Co., which operated its custom

near Cuba City on crude ore and zinc-iron-lead rougher jig concentrates purchased from operators throughout the active areas. The finished zinc and lead concentrates were shipped to smelters in Illinois, and the iron concentrates went direct to the company sulfuric acid plant adjoining the mill. Besides the crude ore treated in 1944, the company bought 29,345 tons for the Metals Reserve Company stock pile; this ore is not included in the production for 1944 shown in the tables of this chapter but will be credited to that for the year in which the ore is reduced to concentrates of smelting grade.

Output from the Northern Illinois area in 1944 totaled 47,993 tons of crude ore yielding 3,123 tons of finished zinc concentrates and 131 tons of lead concentrates; production, in terms of recoverable metals, was 1,693 tons of zinc and 93 tons of lead, compared with 1,152 and 4 tons, respectively, in 1943. The Wisconsin output is given in the tables that follow.

Shippers of Wisconsin rougher jig concentrates to the Vinegar Hill mill in 1944 comprised the C. F. & H. Mining Co. (Mulcahy mine), New Lucky Hit Mining Co. (Coughlin, Wilkins), New Birkett Mining Co., Liberty Mining Co., Wipet Mining Co., and Nightingale tailing mill (Crahall tailings). The principal Wisconsin shippers of crude ore to the mill were Gill Bros. (James mine), Cuba Mining Co. Andrews, B. A. T., Mulcahy No. 2), Piquette Mining Co. (Trego), Meloy & Baker (Hoskins, Martin), Thompson Mining Co., Deuce Mining Co., Carter & Meloy (Leadmine), Van Gordon Mining Co. (Little Joe), Galena Level Mining Co., Mifflin Mining Co. (Defense), and Curwen Mining Co.

The Dodgeville Mining Co. operated steadily its leased group of Dodgeville city lots and 150-ton jig and flotation mill. The W. E. Faithorn mill at the Champion mine near New Diggings, equipped with jigs and flotation machines, operated on old tailings from May through September and on mine rock during November and December. The Little Benny Mining Co. Monroe mine and jig mill were operated from January to August; the jig concentrates were re-treated in the company flotation mill at New Diggings. The Chestnut Hill Zinc Co. treated old tailings in its 200-ton flotation mill near Shullsburg. The new Coker 2,000-ton tailing mill of the United Milling & Mining Co. at Livingston began operating in June and ran steadily after the equipment was adjusted and minor alterations were made. The mill is described in a recent publication.¹

The Bureau of Mines, in cooperation with the Geological Survey, continued its exploration program. Wisconsin properties drilled in 1944 included the Andrew and North Coker at Livingston, Bickford and Defense at Mifflin, Coughlin near Shullsburg, Crescent near Rewey, and Last Chance at Arthur. Geophysical prospecting was done in the Mifflin-Livingston area. At the old Gordon copper mine, Douglas County, the Bureau repaired an old shaft and unwatered, cleaned out, and explored underground workings in an effort to evaluate the showing of several fissures containing native copper. Mining will be conducted to obtain samples for mill tests in a mill erected at the mine.

¹ Most of the ore mined in Wisconsin in 1940-44 was first treated in gravity-concentration mills producing bulk concentrates which were re-treated by flotation.

² In calculating metal content of the ores from assays allowance has been made for smelting losses of both lead and zinc. In comparing the values of ore and metal it should be borne in mind that the value given for the ore is that actually received by the producer, whereas the value of the lead and zinc is calculated from the average price for all grades.

³ Most of the finished zinc concentrates and part of the lead concentrates produced in Wisconsin in 1942-44 came from a custom mill treating purchased crude ores and low-grade bulk concentrates on which premium payments had been made previously to mine operators; therefore, the value of these concentrates is calculated at market prices. Premium payments not reflected in the value of the finished concentrates amounted to about \$399,000 in 1942, \$1,059,000 in 1943, and \$1,384,367 in 1944 for zinc and \$18,500, \$40,600, and \$71,498, respectively, for lead; part of these payments, however, were for ore which was stock-piled.

Tenor of lead and zinc ore and old tailings milled and concentrates produced in Wisconsin, 1943-44

³ Percentages represent metal content of the ore insofar as it is recovered in the concentrates.

⁴ Most of the finished zinc concentrates and part of the lead concentrates produced in Wisconsin in 1943-44 came from a custom mill treating purchased crude ores and low-grade bulk concentrates on which premium payments had been made previously to mine operators; therefore, the value of these concentrates is calculated at market prices.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN COLORADO

(MINE REPORT)

By RICHARD H. MOTE

SUMMARY OUTLINE

	Page		Page
Summary	301	Metallurgic industry	306
Production of value of metal production	301	Review by counties and districts	311
Production by counties	304	Golden Cycle mill	315
Industry	305	Leadville district	317
Classification	306	Cripple Creek district	323

SUMMARY

Colorado gold production in 1944 fell below that in any year since 1875. Except for the period 1931-33, silver production was the lowest since 1873. With the exception of 1943, production of zinc in 1944 was the largest in any year since 1918. The number of producing lode mines decreased from 235 in 1943 to 196 in 1944; the number of placer mines decreased from 17 to 13.

Comparing 1944 with 1943, gold decreased 19 percent and silver 16 percent in both quantity and value; lead decreased 2 percent in quantity but increased 5 percent in value; zinc decreased 9 percent in quantity and 4 percent in value; and copper increased 2 percent in quantity and 6 percent in value. The total value of the five metals was 8 percent less than in 1943; of the total value zinc represented 51 percent, gold 22 percent, lead 16 percent, silver 9 percent, and copper 2 percent.

Eagle County continued to lead the counties of the State in total value of output of the five metals and ranked first in production of zinc. Lake County continued in second place, was the largest producer of lead, and ranked second to Eagle County in production of zinc. San Juan County was in third place in 1944. Other counties of the leading six, listed in order of total value of output, were Dolores, San Miguel, and Teller. Of the 26 counties producing in 1944, these six contributed 82 percent of the total value of the five metals produced in the State.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold †	Silver ‡	Copper ‡	Lead ‡	Zinc ‡
	Per fine ounce	Per fine ounce	Per pound	Per pound	Per pound
1940	\$35.00	\$20.711+	\$0.113	\$0.050	\$0.063
1941	35.00	4.711+	.118	.057	.075
1942	35.00	4.711+	.121	.067	.093
1943	35.00	4.711+	.130	.075	.108
1944	35.00	4.711+	.135	.080	.114

Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 1, 1937, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.
 ‡ Treasury buying price for newly mined silver.
 ‡ 1944-45: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price paid by Metals Reserve Company for overquota production.

Annual figures for the 5 years ended with 1944 and total production from 1858 are given in the table that follows. To the end of 1944 Colorado had produced more silver than any other State, but the decreased output since that year has forced Colorado to yield first place to Montana.

Mine production of gold, silver, copper, lead, and zinc in Colorado, 1940-44, and total, 1858-1944, in terms of recovered metals

Gold.—Mine production of recovered gold in Colorado decreased from 137,558 fine ounces in 1943 to 111,455 ounces in 1944. The principal gold-producing districts in 1944 were: Cripple Creek, Teller County, which produced 28 percent of the State output; Animas, San Juan County, 25 percent; California (Leadville), Lake County, 18 percent; Upper San Miguel, San Miguel County, 17 percent; Sneffels, Ouray County, 3 percent; Summitville, Rio Grande County, 2 percent; Ten Mile, Summit County, 1 percent; and Buckskin, Park County, 1 percent. Dry and siliceous ores yielded 83 percent of the State total gold; zinc-lead ore, 15 percent; and copper, lead, and zinc ores and small placer operations, 2 percent.

Silver.—Mine production of recovered silver in Colorado decreased from 2,664,142 fine ounces in 1943 to 2,248,830 ounces in 1944. The Creede district, Mineral County, continued to be the largest producer of silver and contributed 23 percent of the State total in 1944. Other principal silver-producing districts were: California (Leadville), Lake County, which produced 22 percent of the State output; Animas, San Juan County, 10 percent; Upper San Miguel, San Miguel County, 8 percent; Red Cliff, Eagle County, 6 percent; Roaring Fork, Pitkin County, 6 percent; Pioneer (Rico), Dolores County, 5 percent; Saffels, Ouray County, 4 percent; and Griffith, Clear Creek County, 4 percent. Dry and siliceous ores yielded 53 percent of the State total silver; zinc-lead ore, 42 percent; lead ore, 4 percent; and copper and zinc ores and small placer mines, 1 percent.

FIG. 1.—Value of mine production of gold, silver, lead, and zinc and total value of gold, silver, copper, and zinc in Colorado, 1870-1944. The value of copper has been less than \$2,000,000 annually, except a few years.

Copper.—The output of recovered copper from mines in Colorado in 1944 was 2,096,000 pounds compared with 2,056,000 pounds in 1943. With the exception of operations in Montrose County, virtually all the copper produced in the State in 1944 was recovered as a by-product from ores mined for their zinc, lead, or precious-metal content. Zinc-lead ore yielded 38 percent of the State total copper; dry and siliceous ores, 38 percent also; copper ore, 21 percent; and lead and zinc ores, 3 percent.

Lead.—The mine production of recovered lead in Colorado was 36,996,000 pounds in 1944 compared with 36,064,000 pounds in 1943. The Leadville district, Lake County, continued to be the largest lead-producing area in the State, followed by the Pioneer (Rico), Dolores County; Animas, San Juan County; Red Cliff, Eagle County; and Upper San Miguel, San Miguel County. The production from each of these districts exceeded 2,000,000 pounds of lead, and together they furnished 77 percent of the State output in 1944. Zinc-lead ore yielded 71 percent of the State total lead; dry and siliceous ores, over 23 percent; lead ore, nearly 6 percent; and copper and zinc ores, 0.11 percent.

Zinc.—The output of recovered zinc from mines in Colorado decreased from 88,188,000 pounds in 1943 to 79,910,000 pounds in 1944. The principal zinc-producing districts in 1944, in order of output, were:

Red Cliff, California (Leadville), Pioneer (Rico), Ten Mile, Upper San Miguel, Animas, Griffith, Buckskin, and Tomichi; these nine districts produced 93 percent of the State total output in 1944. Zinc and zinc-lead ores yielded 96 percent of the State total zinc, and dry and siliceous ores 4 percent.

MINING INDUSTRY

The shortage of labor at the mines and mills in Colorado in 1944 was more critical than at any time since the entry of the United States into World War II and was the greatest single factor affecting the production of metals during the year. In addition to the general scarcity of labor, the quality of available replacements at the mines and mills was far below standard. Absenteeism in varying degrees of severity plagued virtually every producing property. Some of the larger operators reported absenteeism as high as 15 percent during certain periods of the year. The nonferrous metal-mining situation in Colorado in 1944, however, was not without some encouraging aspects, of which the most important were: The marked increase in output of zinc and lead in Lake County, the largest production in any year since 1930; the successful development program at the Colorado Mining Co. Black Bear mine in San Miguel County, carried out through extension of the Treasury tunnel (Ouray County), which opened up a large potential source of zinc-lead-copper ore; and the custom milling program of the Resurrection Mining Co., which stimulated the mining of zinc-lead ore in Summit and Lake Counties by providing a market for ore economically unprofitable for direct smelting.

The general policy of the Quota Committee pertaining to the premium-price plan for overquota production of domestic copper, lead, and zinc as revised in 1943 prevailed throughout 1944. The latter part of the year found the producers increasingly apprehensive over the future for premiums on these three metals. Specific concern was evident over the 30-day cancellation clause of all except the basic A premium.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Colorado in 1944, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore.....	557,810	88,621	460,792	578,134	6,372,159	3,113,761
Dry and siliceous gold-silver ore.....	20,930	3,509	54,838	44,976	394,636	-----
Dry and siliceous silver ore.....	62,124	576	670,406	179,072	1,553,062	352,000
	640,864	92,706	1,186,036	802,182	8,319,857	3,465,766
Copper ore.....	7,880	91	27,286	431,814	700	-----
Lead ore.....	11,123	1,313	90,844	27,267	1,951,418	-----
Zinc ore.....	5,939	167	3,544	32,336	37,529	1,352,953
Zinc-lead ore.....	884,616	16,835	941,030	802,401	25,086,496	75,091,282

Total, placers.....	-----	343	90	-----	-----	-----
	1,550,422	111,455	2,248,830	2,096,000	35,396,000	79,910,000
Total, 1943.....	1,631,318	137,558	2,664,142	2,056,000	36,064,000	88,188,000

METALLURGIC INDUSTRY

Of the 1,550,422 tons of ore mined in 1944 in Colorado, 624,696 tons (40 percent) were treated at concentrating plants and 890,913 tons (58 percent) at amalgamation and cyanidation mills with concentrating equipment; 34,813 tons (2 percent) were shipped crude to smelters. The Arkansas Valley lead bullion-leady copper matte smelter at Leadville purchased most of the gold, silver, and gold-silver-lead-copper ore and concentrates shipped to smelters during the year. The quantity of zinc-lead ore sold or treated increased from 613,750 tons in 1943 to 884,616 in 1944, zinc ore from 4,378 tons to 5,939, and copper ore from 3,008 tons to 7,880; dry and siliceous ores decreased from 994,826 tons to 640,864, and lead ore from 15,291 tons to 11,123.

Of the ore treated at concentrating plants, 401,182 tons were zinc-lead ore, 147,165 tons dry gold ore, 50,679 tons dry silver ore, 20,872 tons dry gold-silver ore, 3,217 tons zinc ore, and 1,581 tons lead ore.

Mine production of metals in Colorado in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Ore amalgamated ¹	810,091	35,323	7,510	-----	-----	-----
Sands and slimes cyanided ²	200,014	6,988	16,413	-----	-----	-----
Concentrates smelted.....	142,856	64,472	2,028,390	1,509,480	32,817,194	79,775,376
Ore smelted.....	34,813	4,329	196,427	586,520	2,578,806	134,624
Placer ³	-----	343	90	-----	-----	-----
	-----	111,455	2,248,830	2,096,000	35,396,000	79,910,000
Total, 1943.....	-----	137,558	2,664,142	2,056,000	36,064,000	88,188,000

¹ Quicksilver used by amalgamation mills was 1,812 pounds. Placer mines used approximately 12 pounds.

² Cyanide (in terms of 96 to 98 percent NaCN) used was 195,671 pounds.

³ Comprises 113,869 tons of sands and slimes from ore first roasted and amalgamated and 86,145 tons of selective-flotation tailings.

The destination and treatment of concentrates and ore produced by operators in the State are discussed in the following review by counties and districts.

All the placer gold and silver produced in Colorado in 1944 was recovered by small-scale hand methods. Figures for the quantity of gravel handled at these operations during the year are not obtainable.

The production of metals from amalgamation and cyanidation mills (with or without concentration equipment) in Colorado in 1944, in terms of recovered metals

ADAMS COUNTY

Sand and gravel handled in the washing plant of the Brannan Sand & Gravel Co. on Clear Creek north of Denver yielded gold as a byproduct in sluices operated throughout 1944 by a lessee.

BOULDER COUNTY

Central (Jamestown) district.—All gold, silver, copper, and lead produced in the Central district in 1944 were recovered as byproducts of fluorspar mining. The Argo, Brown Spar, and Emmett mines were operated by H. M. Williamson & Son for the production of fluorspar; lead-silver concentrates recovered from the milling of the fluorspar were shipped to the Leadville smelter.

Gold Hill district.—Virtually all the zinc produced in the Gold Hill district and Boulder County in 1944 came from the Gardner mine, worked under lease by Griswold & Stromberg throughout the year. A total of 972 tons of ore containing 351 ounces of gold, 1,394 ounces of silver, 1,058 pounds of copper, 31,932 pounds of lead, and 45,986 pounds of zinc was shipped to the Golden Cycle custom mill at Colorado Springs. Other mines that shipped to the Golden Cycle mill were the Black Cloud, Tammany, and Home Sweet Home. W. E. Brewster made one small shipment of bullion to the Denver Mint from the Henna property.

Sugar Loaf district.—All the ore produced in the Sugar Loaf district in 1944 was shipped to the Golden Cycle mill for treatment. The Alpine Horn mine, largest producer of gold in the district in 1944, was operated for 6 months during the year by L. E. and P. C. Ward. Small production was reported from the Nancy group and the Poor-man mines.

Ward district.—The Ward United Mines Co. operated the Utica and Boston mines until August, when lack of manpower and equipment forced the operators to close the property; 260 tons of dry gold ore containing 346 ounces of gold, 263 ounces of silver, and 6,154 pounds of copper were shipped to the Leadville smelter. The company 25-ton concentration-flotation mill was not operated during 1944. An operator on the Idaho claim made one small shipment to the Leadville smelter.

CHAFFEE COUNTY

Chalk Creek district.—M. K. McIver, lessee on the Mary Murphy mine, shipped 36 tons of zinc-lead ore containing nearly 12 ounces of gold, 354 ounces of silver, 536 pounds of copper, 6,149 pounds of lead, and 12,155 pounds of zinc to a custom mill at Midvale, Utah. During the summer of 1944 the Minerals Recovery Co. of Houston, Tex., installed a 1,000-ton Humphreys spiral gravity-concentration plant at the Mary Murphy mill to treat old mill tailings on the property. Severe winter weather prevented the plant from operating in 1944.

Granite district.—The production of the Granite district in 1944 came from a small lot of amalgam shipped to the Denver Mint from the Monogram lode by Leland A. Wilcox.

Monarch district.—The largest producer of gold, silver, copper, and zinc in Chaffee County in 1944 was the Garfield mine 1 mile north of Garfield, operated continuously throughout the year by Burleson Bros. A total of 1,735 tons of zinc-lead ore containing 89 ounces of gold, 4,784 ounces of silver, 15,981 pounds of copper, 48,674 pounds of

lead, and 381,719 pounds of zinc was shipped to the Golden Cycle mill for treatment. The Hawkeye mine, also operated by Burleson Bros., was a consistent producer of crude lead ore which was shipped to the Leadville smelter. Several shipments of old smelter slag were sent from the Salida smelter site to a lead smelter in Utah.

CLEAR CREEK COUNTY

Argentine district.—The only productive operation in the Argentine district in 1944 was that of O. Barlow Wilmarth on the National, Sussex, and Newcastle claims in Grizzly Gulch 8 miles southwest of Georgetown. Zinc-lead ore produced was concentrated at the Chicago Creek custom mill; the bulk concentrate was shipped to the Midvale (Utah) custom concentrator for further treatment.

Griffith district.—The largest producer of zinc and lead in the Griffith district and in Clear Creek County was the Mendota mine at Silver Plume, operated continuously during 1944 by Wallace K. Howard. The ore produced was treated in the 60-ton Watrous gravity-concentration mill; zinc-lead concentrates were shipped to the Midvale (Utah) custom concentrator for further treatment, and lead concentrates were shipped to the Leadville smelter. The Mile High Mining Co. continued to operate the Smuggler mine and Silver Leaf mill throughout 1944. Zinc and lead concentrates were produced and shipped to the Amarillo (Tex.) and Leadville smelters. A small tonnage of lead ore from the Dives-Pelican mine at Silver Plume was treated at the Commonwealth mill north of Georgetown. Several truckloads of lead ore from the New Boston mine were treated at the Golden Cycle mill.

Idaho Springs district.—Nearly 81 percent of the ore mined at the 11 producing properties in the Idaho Springs district in 1944 was milled at the Golden Cycle mill in Colorado Springs. Several custom mills in the district operated intermittently during the year; these were the Chicago Creek, Silver Spruce, and Ruth. The Golden Cycle mill received ore shipments during the year from the Idaho Bride, Brighton, Silver Age, Franklin 73, East Lake, Bald Eagle, and Stanley mines. Crude smelting ore was shipped to the Leadville and Tooele (Utah) smelters from the Idaho Bride, Oregon, Silver Age, Franklin 73, Silver Gem, and Salisbury properties.

Montana district.—Edgar Endy shipped to the Leadville smelter one small lot of dry gold-silver ore recovered during development at the Rainbow mine. Lead concentrates recovered from the milling of dry silver ore from the Silver King mine and Jo Reynolds dump were shipped to the Leadville smelter.

Trail Creek district.—The Harrison Croesus Mining Co. operated the Ben Harrison and Croesus claims on Trail Creek 4 miles southwest of Idaho Springs from June 28 to December 31, 1944. Zinc-lead sulfide ore totaling 249 tons was concentrated at the Golden Cycle mill in Colorado Springs. Ore recovered during development at the Lone Tree and Diamond Mountain properties was concentrated at local custom mills; concentrates produced were shipped to the Leadville smelter.

CUSTER COUNTY

Hardscrabble district.—The Lady Franklin mine near Westcliffe, largest producer of gold, silver, lead, and zinc in Custer County in 1944, was operated until July 1 by A. M. Poston and from September

through December by George L. Beardsley. A total of 3,648 tons of zinc-lead ore was shipped to the Golden Cycle mill for concentration. Crude zinc-lead ore also was shipped to the Golden Cycle mill from the Keystone and Bull Domingo mines. H. R. Henning operated the Defender property intermittently during the year; 120 tons of lead ore containing 4 ounces of gold, 2,217 ounces of silver, and 53,588 pounds of lead were shipped to the Leadville smelter. A small lot of lead ore also was shipped to the Leadville smelter from the Passiflora mine.

DOLORES COUNTY

Pioneer district (Rico).—The Rico Argentine Mining Co. operated its group of mines and 135-ton selective-flotation mill continuously in 1944 and shipped lead concentrates to the Leadville and zinc concentrates to the Amarillo (Tex.) smelters. Three shafts (the Atlantic Cable, Van Winkle, and Argentine No. 2) and three tunnels (the Blaine, Pro Patria, and Revenue) were in use during the year. Ore milled totaled 36,558 tons averaging 17 percent zinc and 10 percent lead. In addition to the usual wartime operating difficulties, the company was burdened with several problems uncommon in ordinary mining operations. The narrow-gage railroad serving the Rico area threatened to discontinue service for lack of operating capital; in order to get service from the county the company was forced to provide a substitute for the county treasurer, subsidize an undersheriff for policing the community, and provide funds for the teachers in the community public school. Markey Bros. operated the Yellow Jacket group under lease from the Rico Argentine Mining Co. and shipped crude zinc-lead ore to the Midvale (Utah) concentrator. Zinc-lead ore also was shipped to the Midvale mill from the Swan dump.

EAGLE COUNTY

Red Cliff district (Battle Mountain).—The Red Cliff district produced 51 percent of the total output of recovered zinc in Colorado in 1944 and continued to rank first among Colorado districts in value of production of the five metals. The New Jersey Zinc Co. Empire Zinc Division operated its Eagle mine and 600-ton underground selective-flotation mill continuously during the year. Zinc concentrates were shipped to the company smelters at Depue, Ill., and Palmerton, Pa., and lead concentrates were shipped to the Leadville smelter. Copper-iron-silver-gold sulfide ore was shipped to the Leadville smelter and the Garfield (Utah) and Murray (Utah) smelters.

EL PASO COUNTY

GOLDEN CYCLE MILL

The Golden Cycle mill at Colorado Springs operated throughout the year on company and custom ores from nearly all mining districts in the State; 221,543 tons of ore were treated in 1944 as compared with 287,939 tons in 1943. Of the total ore treated, 113,565 tons (226,908 tons in 1943) were company and custom gold-[silver]-sulfotelluride ores from the Cripple Creek district (Teller County), and 107,978 tons (61,031 tons in 1943) were miscellaneous zinc-lead and gold ores from Boulder, Chaffee, Clear Creek, Custer, Fremont,

Gilpin, Gunnison, Lake, Park, Pitkin, Saguache, San Juan, and Summit Counties. The 500-ton selective-flotation unit of the mill handled 107,561 tons of zinc-lead sulfide ores in 1944. The ores purchased vary in character; consequently, the metallurgy is not always the same. Ores from Cripple Creek are roasted, amalgamated,¹ and cyanided. Complex ores containing base metals are treated by selective flotation; the tailings from this operation are separated into sand and slimes and cyanided.

FREMONT COUNTY

Cotopaxi district.—The Monarch Galena Co. operated the Cotopaxi mine in the Cotopaxi district throughout 1944 and shipped 2,688 tons of zinc ore containing 37 ounces of gold, 39,404 pounds of copper, and 1,278,274 pounds of zinc to the Golden Cycle mill. The mine is developed by a 400-foot tunnel; 200 feet of drifts were driven during the year.

Grape Creek district.—Christison & Van Buskirk operated the Horseshoe mine, 9 miles southwest of Canon City, throughout 1944; 1,384 tons of zinc-lead ore containing 33 ounces of gold, 672 ounces of silver, 15,005 pounds of copper, 68,698 pounds of lead, and 194,296 pounds of zinc were shipped to the Golden Cycle mill.

GILPIN COUNTY

Southern districts (Blackhawk, Central City, Nevadaville, Russell Gulch).—The Widow Woman mine, operated throughout 1944 by the G. S. & G. Mining Co., was the largest producer in Gilpin County. Zinc-lead sulfide ore was shipped to the Golden Cycle mill for concentration. The Lu Ev Mining Co. mined the Hope and Powers claims throughout the year and shipped copper ore to the Garfield (Utah) smelter. The Boodle mine was active, and in addition to shipping zinc-lead ore to the Golden Cycle mill the operators continued work on the Boodle mill. Other properties that shipped ore to the Golden Cycle mill included the Jennie Blanch, West Notaway, Meeker-Success, and Cleveland mines. Lead ore was shipped to the Leadville smelter from the Cleveland, Jennie Blanch, Philadelphia, and Meeker-Success mines. Intermittent work at the Old Town group yielded 78 tons of dry gold ore which were shipped to the Leadville and Garfield (Utah) smelters.

Northern district.—A clean-up at the Perigo mill yielded a small amount of amalgam bullion which was shipped to the Denver Mint.

GUNNISON COUNTY

Rock Creek district.—The Colorado Zinc Co. leased and operated the Lucky Boy mine near Marble in October and November 1944. Zinc-lead ore totaling 44 tons and containing 167 ounces of silver, 4,686 pounds of lead, and 11,805 pounds of zinc was shipped to a custom concentrator at Bauer, Utah. A small lot of lead ore was shipped to the Leadville smelter. A. J. Betz worked the Catalpa mine from June 15 to December 31; 73 tons of zinc-lead ore containing 1 ounce of gold, 374 ounces of silver, 1,316 pounds of copper, 8,954 pounds of lead, and 12,760 pounds of zinc were shipped to the Golden Cycle mill and the Bauer (Utah) custom concentrator.

¹ Free gold is saved on lightweight cotton-flannel blankets and amalgamated in an iron arrastre.

Taylor Park district.—John Lambertson operated the Star mine on Italian Mountain continuously during 1944; 117 tons of lead ore were shipped to a smelter in Utah. Lambertson also worked the Bull Domingo claim and shipped 27 tons of lead ore to the Leadville smelter.

Tomichi district.—The Callahan Zinc-Lead Co. continued to operate its Akron mine at White Pine during 1944. Production came from the Erie-Sunset and Lost Contact claims. The mine is developed by a 3,000-foot tunnel with 250 feet of raises and 400 feet of drifts; 350 feet of new drifts and 250 feet of tunnel were completed during the year.

HINSDALE COUNTY

Galena district.—The Base Metal Corp. operated the Ute and Ulay group and 100-ton selective-flotation mill from April 15 to October 1. Zinc-lead ore milled totaled 2,200 tons and yielded 127 tons of zinc-lead concentrates.

LAKE COUNTY

California (Leadville) district.—One furnace of the American Smelting & Refining Co. Arkansas Valley lead bullion-lead copper matte smelter was operated continuously throughout 1944. Except for a small shipment of concentrates received from South Dakota, all material treated came from Colorado mines. Receipts of ore and concentrates totaled 67,960 tons, compared with 80,433 tons in 1943.

The Resurrection Mining Co. maintained continuous production at its Resurrection mine and 600-ton selective-flotation mill during the year. The mill has two 300-ton units (one completed in January 1944), but only one operated most of the year. In addition to concentrating Resurrection ore, the mill treated custom ore from producers in the Ten Mile, Breckenridge, and Montezuma districts, Summit County; the Griffith district, Clear Creek County; and from the Leadville district. The Resurrection mine is developed by the 1,323-foot Resurrection vertical shaft (six operating levels) and the 4-mile Yak tunnel, which connects the mill with the main shaft at the 850-foot level. Development completed during the year included 208 feet of inclined winze, 1,670 feet of drifts, 869 feet of raises, and 3,192 feet of diamond drilling.

The Ore & Chemical Co. 1,000-ton Heavy Media separation plant was operated continuously in 1944 on ores from the South Moyer, Tucson, Accident, Colonel Sellers, Greenback, and Wolfstone dumps. Approximately 375,000 wet tons of dump material were treated, resulting in the production of about 41,000 tons of bulk concentrates, which were shipped to the Golden Cycle mill at Colorado Springs for selective flotation. The California Gulch Mining & Milling Co. operated its two gravity- and flotation-concentration and amalgamation mills—one 75- to 125-ton capacity and one 450-ton capacity—throughout the year on ores from the Ibex and Colonel Sellers dumps. John Hamm Mining & Milling, Ltd., operated its 600-ton gravity-concentration mill the entire year on ore from the Wolfstone and Maid of Erin dumps. Bulk concentrates produced were shipped to the Resurrection Mining Co. and Golden Cycle mills for further concentration.

The Golden Cycle mill at Colorado Springs also treated ore from the Fortune and Little Johnny mines. The principal shippers of

smelter ore to the Leadville smelter (in approximate order of tonnage) were the Ibox, Dolly B, Commerce, New Monarch, Rock & Dome, Golden Eagle, Little Ellen, Valley, Adelaide, Little Johnny, Tucson, and Treasure Vault dump.

Operations at the projected 17,000-foot Leadville drainage tunnel continued on a three-shift basis throughout the year. Progress was slower than anticipated owing to the fractured condition of the rocks, making it necessary to gunite and concrete the walls of the tunnel at some points to consolidate the rocks and check the flow of water. At approximately 2,200 feet from the portal, a cave occurred that could not be controlled. The heading was bulkheaded and the bad ground bypassed successfully. At the end of 1944 the tunnel heading had advanced 2,673 feet from the portal and was being driven in the Gilman sandstone formation which permitted more rapid progress.

LA PLATA COUNTY

California (or La Plata) district (Hesperus, La Plata).—Bert Thompson worked the Bessie G mine and shipped 8 tons of dry gold ore, containing 163 ounces of gold and 107 ounces of silver, to the Midvale (Utah) smelter.

MINERAL COUNTY

Creede district.—The Emperius Mining Co., which in 1944 controlled nearly all mining properties in the Creede district, operated its 100-ton flotation mill the entire year on ore from the Amethyst, Bachelor, Commodore, Equinox, New York, Last Chance, Del Monte, Aspen, Happy Thought, and Robinson mines. Lead-silver-gold concentrates produced were shipped to the smelter at Leadville. The company also shipped lead-silver ore to the Leadville smelter from the Amethyst, Commodore, Last Chance, Del Monte, Aspen, and Robinson mines. The company continued work on its transportation tunnel at the lower end of Willow Creek Canyon; over 1 mile of the proposed 2½ miles of the tunnel has been completed. A complete surface plant, consisting of ore bins, machine and blacksmith shops, lighting plant, drying and sorting rooms, compressor plant, and locomotive shops, is near completion at the portal. The Ridge Leasing Co. operated the Ridge mine during the first part of the year and shipped 92 tons of zinc-lead ore to the Midvale (Utah) custom concentrator.

MONTROSE COUNTY

La Sal district.—The New Cashin Mines, Inc., operated the Cashin group of claims throughout the year and shipped 7,687 tons of copper fluxing ore to the Garfield (Utah) smelter.

OURAY COUNTY

Red Mountain district.—Seven mines were producing in the Red Mountain district in 1944. Among the larger operators were Red Mountain Mines, Inc., which shipped ore from the Genesee-Vanderbilt and Yankee Girl claims to the Leadville and Midvale (Utah) smelters and to the Midvale (Utah) custom concentrator; and the Denver Engineering Co., which operated the San Antonio mine through the Koehler tunnel at the top of Red Mountain Pass during

the early part of the year. Other producers shipping ore to the Leadville smelter and to the Midvale (Utah) custom mill were the Balm of Gilead, Lost Day, Yankee Boy, Beaver-Belfast, and Ida L mines.

Sneffels district.—The largest producer in Ouray County in 1944 was the Camp Bird mine and 100- to 125-ton amalgamation-flotation mill operated by King Lease, Inc. (See Minerals Yearbook, 1941, p. 348, for methods of ore treatment.) Concentrates were shipped to the International Smelting & Refining Co. lead smelter at Tooele, Utah; bullion produced was shipped to the Denver Mint. Development during the year included 443 feet of raises, 225 feet of drifts, and 763 feet of diamond drilling.

Uncompahgre district.—The Franz brothers, operating as the General Ore Reduction Co., continued to run their custom mill in Ouray in 1944. Lack of ore curtailed operations during the year. Lead-silver-zinc concentrates produced were shipped to the Midvale (Utah) mill and smelter. The McCullough Lease continued to treat old mill tailings from the Wanakah dump and to ship the concentrates to the Midvale (Utah) smelter. Julius Sonza, operating the Bachelor Consolidated mine under lease, installed a hoist and retimbered and relined the Bachelor shaft. Ore produced during the year was milled at the General Ore Reduction Co. mill. E. W. Creel operated the Micky Breen mine in Poughkeepsie Gulch from May 15 to December 31; 1,135 tons of zinc-lead ore were shipped to the General Ore Reduction Co. mill.

PARK COUNTY

Buckskin district.—The Buckskin Joe Mines, Ltd., operated the Phillips group of mines in Buckskin Gulch and the Alma-Betts 65-ton selective-flotation mill in Mosquito Gulch throughout 1944. The products of the mill were zinc, lead, and iron concentrates. The company also operated the Baxter mine under lease and treated the ore in the Alma-Betts mill. Miller & Logue continued to operate the Red Cross mine; 324 tons of zinc-lead ore containing 14 ounces of gold, 48 ounces of silver, 1,340 pounds of copper, 24,825 pounds of lead, and 46,091 pounds of zinc were shipped to the Golden Cycle mill at Colorado Springs for concentration.

Consolidated Montgomery district.—The Magnolia Gold Mining Co. operated the Lee Goss lode from January through October; crude milling ore was shipped to the Golden Cycle plant for concentration, and several shipments of dry gold ore were made to the Leadville smelter.

Mosquito district.—The London Extension Mining Co. worked the Orphan Boy mine throughout most of 1944, and shipments of zinc-lead ore were made to the Golden Cycle mill. Dump material from the North London mine was treated in the Record mill by Alma Mills, Inc.; 186 tons of concentrates produced were shipped to the Leadville smelter. A clean-up during the dismantling of the London mill yielded concentrates and bullion which were shipped to the Leadville smelter and the Denver Mint. A small production of bullion was reported from the Three Brothers claim.

Pulver district.—The Great Western mine on Wilkerson Pass 10 miles west of Lake George was operated from April through December by O. N. Sandholm; 1,354 tons of zinc ore containing 18 ounces of gold, 26,356 pounds of copper, 3,564 pounds of lead, and 176,403 pounds of zinc were shipped to the Golden Cycle mill.

PITKIN COUNTY

Roaring Fork district (Aspen).—The Midnight Mining Co. operated the Midnight mine and 50-ton selective-flotation mill on Richmond Hill continuously 6 days a week in 1944. The mine produced 8,303 tons of silver-lead-zinc ore averaging 15.1 ounces of silver to the ton, 3.7 percent lead, and 4.5 percent zinc. Lead and zinc concentrates were shipped to the Leadville and Amarillo (Tex.) smelters. Herron Bros. operated its 150-ton gravity-concentration mill north of Aspen throughout most of the year on dump material from the Henry Clay mine; bulk concentrates produced were shipped to the Golden Cycle mill for further treatment. Development at the Mountain Ranger group of claims recovered 2 tons of lead ore, which were shipped to the Leadville smelter. Lime fluxing material, carrying silver and lead, was shipped to the Leadville smelter from the Aspen Leases during the first part of the year.

RIO GRANDE COUNTY

Summitville district.—The Gold Links Mining Co. (under special grant from the War Production Board) operated the Little Annie Group of mines and 50-ton amalgamation and concentration-flotation mill the entire year. The mine produced 1,769 tons of ore averaging 1.2 ounces of gold and 0.65 ounce of silver to the ton and 0.45 percent copper; copper concentrates produced were shipped to smelters in Utah and California and in Leadville, Colo. Regular shipments of amalgamation bullion were made to the Denver Mint. The Jasper Mining Co. made one small shipment of dry gold ore from the Guadalupe and Miser Tunnel claims to the Leadville smelter.

ROUTT COUNTY

Milbank Franz continued to work the Greenville mine in the Hahns Peak area during 1944; 916 tons of zinc ore containing 6 ounces of gold, 1,010 ounces of silver, 10,284 pounds of copper, 22,439 pounds of lead, and 217,138 pounds of zinc were shipped to the Midvale (Utah) custom concentrator.

SAGUACHE COUNTY

Kerber Creek district (Bonanza).—Brugger & Keserich operated the Bonanza dump from January through August and made regular shipments to the Golden Cycle mill and the Midvale (Utah) custom concentrator. Other properties that shipped ore to the Golden Cycle mill during 1944 included the Cora, Erie, and Rawley mines. The Pratt-Bonanza Mining & Milling Co. operated the St. Louis mine under lease throughout the year and shipped 622 tons of zinc-lead ore to the Combined Metals Reduction Co. custom mill at Bauer, Utah. Several shipments of lead ore were made to the Leadville smelter. Some production from the Erie, Bonanza dump, Rawley, and St. Louis properties also was shipped to the Midvale (Utah) custom concentrator.

SAN JUAN COUNTY

Animas district.—The Shenandoah-Dives mine continued in 1944 to be the chief producer of metals in San Juan County. The company 700-ton selective-flotation mill on the Animas River near Silver-

ten treated 142,635 tons of ore from the Shenandoah-Dives consolidated group of claims on King Solomon Mountain. The lead and zinc concentrates produced were shipped to the Leadville and Amarillo (Tex.) smelters and contained 25,929 ounces of gold, 130,855 ounces of silver, 321,166 pounds of copper, 2,347,860 pounds of lead, and 634,887 pounds of zinc. Custom ore milled at the company mill during 1944 came from six mines in the Animas, Eureka, and Ice Lake Basin districts. The Highland Mary Mines, Inc., operated its group of mines and flotation mill in Cunningham Gulch from June through December. During the year the operators added a new ball mill and classifier to the mill, enlarging the daily capacity of the plant from 70 to 100 tons. A total of 5,762 tons of ore, averaging 0.22 ounce of gold and 4.10 ounces of silver to the ton, 0.10 percent copper, and 0.84 percent lead, was milled. Concentrates from this property were shipped to the Leadville smelter. The Denver Equipment Co. continued to operate the 100-ton Pride of the West selective-flotation mill at Howardsville on company ore from the Pride of the West group. The ore milled totaled 24,348 tons and averaged 0.061 ounce of gold and 3.76 ounces of silver to the ton, 0.21 percent copper, 5.10 percent lead, and 1.25 percent zinc. Other mines that operated in the Animas district in 1944 and shipped ore either to the Shenandoah-Dives mill or to the Golden Cycle mill at Colorado Springs were the Lark, Mogul, Little Fannie, and Kittimac.

Eureka district.—All the ore produced at mines in the Eureka district in 1944 was sold either to the Shenandoah-Dives or Golden Cycle mill. The three producers, in order of output, were the Fore-some Mining Co. (Columbus mine), A. R. Walker (Mountain Queen mine), and Vaughn Jones (Lead Carbonate mine).

Ice Lake Basin district.—Esmeralda Lease operated the Bandora mine from July 3 to November 15; 202 tons of zinc-lead ore were shipped to the Shenandoah-Dives mill.

SAN MIGUEL COUNTY

Upper San Miguel district (Telluride).—Telluride Mines, Inc., continued to operate during 1944 its 550-ton amalgamation and gravity-and flotation-concentration mill at Pandora 2½ miles east of Telluride. During most of the year the company operated the mine only one shift per day because of lack of underground labor and of absenteeism. The ore milled came from the Smuggler Union, Cimarron, and Montana properties. Mine production was augmented by treating dump material from the Tom Boy mine. Lead concentrates produced were shipped to the Leadville and Midvale (Utah) smelters; zinc concentrates were shipped to the Amarillo (Tex.) and Great Falls (Mont.) smelters. Alta Mines, Inc., continued operations at its Alta-St. Louis group and 100-ton gravity- and flotation-concentration mill. Production was restricted, however, by an acute shortage of mine and mill labor. A small quantity of bullion recovered by amalgamation was shipped to the Denver Mint from the Allegheny mine.

The Sunshine Mining Co., as agent for the Metals Reserve Company, continued the development program at the Treasury tunnel (Red Mountain district, Ouray County), which was extended in 1943 to intersect the Black Bear vein beneath the old Black Bear workings in Ingram Basin on the Telluride side of Columbia Mountain. On

July 1, 1944, the Idarado Mining Co., owner of the Black Bear mine and Treasury tunnel, liquidated all financial advances made by the Metals Reserve Company and assumed complete control of its property. Rehabilitation of the 250-ton selective-flotation mill at the portal of the tunnel was in progress the latter part of the year. The surface plant and mill are in Ouray County, but mining is in San Miguel County.

SUMMIT COUNTY

Breckenridge district.—The largest operation in the Breckenridge district in 1944 was the Lilly & Moran lease on the Sally Barber mine; 1,502 tons of zinc-lead ore were shipped to a smelter and custom mill in Utah. The Garvie London Gold Mining Co. continued to develop the Country Boy mine; crude zinc ore was milled at the Resurrection Mining Co. mill in Leadville and the Golden Cycle mill at Colorado Springs. A lessee on the Jumbo claim recovered a small amount of amalgam bullion and made several shipments of dry gold ore to the Leadville smelter. Horn Bros. operated the Minnie B mine from June through October and shipped 57 tons of dry gold-silver ore containing 16 ounces of gold, 1,882 ounces of silver, and 983 pounds of lead to the Leadville smelter.

Green Mountain district.—Walter McDaniel continued producing zinc ore from his Big Four mine on Green Mountain 17 miles south of Kremmling.

Montezuma district.—The Florado Mining Co. operated the Pinnacle claim and its 100-ton flotation mill 6 months during 1944 and shipped lead concentrates to the Leadville smelter. The Rogers Mines, Inc., worked the Morgan group of claims from January through April and shipped zinc-lead ore to the Golden Cycle mill at Colorado Springs. Properties in the Montezuma district from which zinc-lead ore was trucked to the Resurrection Mining Co. mill at Leadville were the New York, Ida Belle, and Rose. Twenty-nine tons of zinc-lead ore were shipped to the Midvale (Utah) custom mill from the Bell of California group. In addition to shipping 20 tons of zinc-lead ore to the Midvale (Utah) custom mill, Easter & Milner, operating the Silver Wing mine, made a small shipment of lead concentrates to the Leadville smelter. Lessees on the New York mine shipped dump material to the Leadville smelter and the Midvale (Utah) custom mill. Other properties in the Montezuma district reporting small production were the Empress and Erickson mines.

Ten Mile (Kokomo, Robinson) district.—The Wilfley Leasing Co. operated its Wilfley mine at Kokomo continuously in 1944 and shipped crude milling ore to the Resurrection Mining Co. custom mill at Leadville. The Wilfley 75-ton selective-flotation mill was not operated during the year. Control of the Washington and Hancock group (known as the Lucky Strike group) was acquired by the American Smelting & Refining Co. on February 28, 1944, under a purchase contract. Rehabilitation of the Cole-Peterson (Victory) tunnel to open the vein at greater depth was completed during the summer, and in September the company began regular shipments of crude milling ore to the Resurrection Mining Co. custom mill at Leadville. The Kokomo-Kimberly Mines, Inc., operated the Kimberly property throughout the year and shipped ore to the Golden Cycle mill at Colorado Springs. A. R. Rhine worked the Nettie B mine during the year and shipped zinc-lead ore to the Golden Cycle mill. A

lessee on the Golden Queen mine trucked 40 tons of dry silver ore to the Leadville smelter.

Wilkinson district.—Small production of lead ore was reported from the Tariff and Toledo claims.

TELLER COUNTY

CRIPPLE CREEK DISTRICT

The Cripple Creek district yielded 28 percent of the total gold production of the State in 1944. From 1891, when gold was discovered in the area, through 1944 it has yielded a total of 18,496,735 fine ounces valued at \$400,960,207, or 48 percent of the State total output of gold from 1858 to 1944, inclusive. In 1944 the district produced 30,886 ounces compared with 45,105 ounces in 1943, 104,455 in 1942, and 133,470 in 1941. The steady decline in production of gold since 1941 largely reflects the effect of the Gold Mining Limitation Order of October 1942 on the mining industry of the Cripple Creek district. The total production of ore from Cripple Creek mines and dumps in 1944 was 113,565 tons, all treated in the Golden Cycle mill (operations reviewed under El Paso County).

MINES REVIEW

Operations of the Golden Cycle Corp., which owns and operates the Golden Cycle mill at Colorado Springs and several mines in the Cripple Creek district, are described in the following extract from its annual report to stockholders for the year ended December 31, 1944 (dated May 7, 1945):

Stockholders were fully informed in the 1943 report relative to Order L-208 and its effect upon our activities. The Golden Cycle Corporation operated during 1944 under a special grant from the War Production Board, but because of the drastic shortage of labor, miners, and materials all of our operations were handicapped and drastically curtailed.

Production of strategic metals.—(1) During 1944 a total of 107,561 tons of complex ore with a gross value of \$1,060,097.81 was purchased from shippers for the production of lead-zinc concentrates. It is significant to note that complex ore purchased during this 12 months period contained the following metals: 21,544,583 pounds of zinc; 8,145,880 pounds of lead; 655,309 pounds of copper; 491,325 ounces of silver; and 6,166 ounces of gold; gross value \$1,060,097.81.

(2) During 1944, 16,113 tons of zinc concentrates were shipped to smelters of the American Zinc Co. located at Dumas, Tex., and Carondelet, Ill.; and 5,430 tons of lead concentrates were shipped to the American Smelting & Refining Co., Leadville, Colo.

(3) Zinc-lead ore for treatment at the Golden Cycle mill at Colorado Springs was received during the year from zinc-lead mines located in and near Leadville, Montezuma, Kokomo, the Bonanza district, Alma, Clear Creek County, San Juan County, and other mineralized areas of Colorado.

(4) The Golden Cycle Corporation did not engage on its own account during the year in the mining of zinc-lead ore. During 1944 the Golden Cycle Corporation purchased the Wilson group of mining claims, located in the Kokomo mining district near Leadville, Colo. Total acreage of these claims is 114. At present a portion of the Wilson property is under lease to the American Smelting & Refining Co.

(5) It is probable that during 1945 the Golden Cycle Corporation will again engage on its own account in the mining of zinc-lead ores. The War Production Board has informed us that at present lead is the most critical of all strategic metals, and, if possible, the Golden Cycle Corporation will do everything in its power to aid in the production of lead so vitally needed for the war at the present time.

Gold-mining operations. *Ajax, Anchoria Leland, Index, and Cameron mines.*—Gold-mining operations in the Cripple Creek mining district were greatly cur-

tailed during 1944. This was due not only to the fact that the number of company men and lessees dropped to the lowest figure in all our history, but also difficulties in obtaining sufficient materials and supplies. No betterment in gold production from the Cripple Creek district can be expected until an adequate supply of labor is secured. This depends upon the cessation of war hostilities first against Germany, and second, against Japan.

Only the Ajax and Anchoria Leland shafts were operated during the year. The Index and Cameron shafts were shut down.

Ajax operation.—Every effort was made to do as much development work as the limited number of men would allow. 4,940 feet of drifts, crosscuts, and raises were driven during the year. Most of the drifting was done on the Bob Tail vein system on the 26th, 27th, and 28th levels of the mine. Development work in this section was satisfactory and a number of ore chutes opened on each of these levels. A majority of the ore shipped during the year came from this development work. Very little stoping was carried on. A small amount of work was done west of the shaft on the New Market system on the 24th, 26th, and 27th levels with some ore being opened in this section of the mine. There still remains a large amount of territory on the deeper levels to be explored when the labor situation permits.

During 1944, 27,417 tons of company ore were shipped with a gross value of \$403,604 and 7,215 tons of lessee ore with a gross value of \$105,754, making a total of 34,632 tons with a gross value of \$509,358.

Anchoria Leland.—All development work on the Anchoria Leland was done by lessees. 1,006 feet of drifts, crosscuts, and raises were driven during the year. Total production was 3,305 tons with a gross value of \$26,201.

Index.—No work was done on the Index during the year. A small amount of dump ore was shipped to the mill.

Cameron.—During 1944 the Cameron gold-mining property was acquired by the Golden Cycle Corporation. It contains approximately 140 acres. No work was done by the company during the year.

Summary of gold-mining operations.—Mining operations on the properties of the Golden Cycle Corporation in the Cripple Creek mining district during 1944 produced a total of 38,181 tons of ore with a gross value of \$536,812.05. Net returns to the corporation from its properties after payment of freight and treatment but before payment of mining costs totaled \$314,324.88.

Carlton drainage tunnel.—During the year wooden timbering in the Carlton drainage tunnel was replaced with steel and the tunnel is now in good shape. It will be necessary to do some additional repair work on the track and water ditch. No serious trouble from loose ground in the near future is anticipated, as the tunnel, generally speaking, is in good shape throughout. The water flow from the Carlton drainage tunnel remains steady at approximately 4,800 gallons per minute. Practically all production from the Ajax and Portland mines during the year came from the area newly drained by the Carlton drainage tunnel. Without this drainage neither property would be operating today.

It is still impossible to forecast with any certainty the future of our corporation during the war period. Stockholders are assured that every effort will be made to continue our activities in connection with producing war necessities, and that every effort will be made to conserve properties and assets of the corporation for the stockholders' best interests, with the hope that with the end of the war operations can again be resumed upon a normal basis.

The annual report of the United Gold Mines Co., an operating and holding company for property scattered throughout the Cripple Creek district, for the year ended December 31, 1944 (dated March 15, 1945), gives the following details on operations at individual mines:

Operating loss for 1944 was \$16,792 vs. \$13,102 in 1943, an increase of \$3,690. This loss was caused by the same factors which operated adversely in 1943; to wit: damage done to the gold-mining industry in the United States and Alaska by Order L-208 entered October 8, 1942, by the Mining Branch of the War Production Board closing the gold mines. While extensions to operate upon a limited basis were subsequently granted the United Gold Mines Co.—due to the fact that practically all able-bodied men in the Cripple Creek mining district had either entered our armed forces or left the district to take higher paying defense jobs, coupled with the difficulty in securing necessary mining supplies, a situation was created which the company could not combat.

It is impossible at this date to make any intelligent forecast for this year. Resumption of gold mining upon a normal basis now depends upon the duration

of the war and when we can secure an adequate supply of labor and materials. It was hoped during the latter part of 1944 that the war with Germany would be over by January 1, 1945, but this did not materialize, and labor and materials have become even more critical than in 1944.

A résumé of our operations for 1944 follows:

Production from the United Gold Mines Co. reached a new low for the year 1944, both in tonnage and value. 67,885 tons were shipped with a gross value of \$478,455 and an average value of \$7.05 per ton. This included 24,048 tons shipped from the Theresa dump, with a gross value of \$75,896 and an average value per ton of \$3.16. Only 43,837 tons were shipped from the various other properties of the United Gold Mines Co. The number of lessees operating on the Portland, Vindicator, and Rose Nicol shafts has fallen to 16, the lowest number in the history of the company.

Portland operation.—Production from the Portland shafts amounted to 10,635 tons with a gross value of \$163,927, of which amount lessees shipped 3,372 tons with a gross value of \$82,088. The company ore came almost entirely from old caved stopes on the 27th, 29th, and 30th levels. 1,889 feet of drifts, crosscuts, and raises were driven by the lessees and company.

Vindicator operation.—Company and lessees shipped 16,708 tons with a gross value of \$111,343. 11,733 tons were shipped by lessees, and 4,974 tons by the company. 2,415 feet of drifts, crosscuts, and raises were driven by the company and lessees during the year.

The main shaft on the Vindicator hoist broke in August but the break was in such a position that hoisting could be carried on on one side. Efforts have been made since that time to obtain a new shaft, but without results to date. A new shaft will have to be placed in the hoist before full-scale operations can be carried on.

Rose Nicol operation.—Operations were carried on at the Rose Nicol shaft on a greatly reduced scale, as were our other properties. 2,104 tons with a gross value of \$23,418 were produced, only 70 tons of which was company ore. 796 feet of drifts, crosscuts, and raises were driven by the company and lessees during the year.

Very little work was done on the various other properties of the United Gold Mines Co. during the year. Some work was done on the Wild Horse and Patti Rosa shafts by lessees.

As pointed out above, no betterment in our situation can be expected until the war ends. The labor situation is daily growing worse. There are of course no young men working in the district today.

The annual report of the Cresson Consolidated Gold Mining & Milling Co. for the 12 months ended December 31, 1944 (dated February 1, 1945), says—

PRESIDENT'S REPORT

As set out in our 1943 annual report, due to the impossibility of securing labor because practically all able-bodied men had left the Cripple Creek district either to enter the armed forces or to take higher-paid defense jobs, plus our inability to secure necessary mining supplies, the Cresson mine was shut down and still remains idle in a standby condition.

Some revenue was derived during the year from war contracts. Considerable work was done during the year retimbering the shaft and preserving the property.

The latter part of 1944 it appeared the German war might be over by January 1, 1945, and we hoped the cessation of hostilities would ease our manpower, miner, and material shortages. However, as stockholders know, more drastic war demands for labor and material have created additional complications for the gold-mining industry. It is impossible at this time to state when the mine can be reopened, since the resumption of mining depends entirely upon securing adequate labor, miners, material, and equipment.

The management will continue to use every effort during this standby period to preserve the company's current financial position and maintain the properties for stockholders' best interests.

Production of Cresson Consolidated Gold Mining & Milling Co., 1903 to December 31, 1944

SUMMARY

The dominating factors in the mine production of gold, silver, copper, lead, and zinc in the Eastern States in 1944 were the shortage of labor supply and the outstanding importance of the metals and other products of the ores to the prosecution of the war. The only output of gold and silver was that recovered as a byproduct from base-metal ores and the 5 ounces of gold produced at placer mines. Most of the copper output continued to come from ores mined chiefly for their iron or their iron, sulfur (recovered as sulfuric acid), and copper content, but considerable copper was derived from straight copper ore and a little from zinc-lead ore; the production from all sources increased 6 percent over 1943. The output of lead—all from zinc-lead ore—increased 29 percent. The combined tonnage of zinc and zinc-lead ores mined decreased 2 percent from 1943; and the total production of zinc, including some from copper-iron-zinc ore, decreased 11 percent. War-essential byproducts derived from zinc and zinc-lead ores included sulfuric acid and cadmium. Variations from 1943 in zinc production in the several States were decreases of 14 percent in New Jersey, 23 percent in New York, and 2 percent in Tennessee and an increase of 6 percent in Virginia. Some of the large zinc and zinc-lead mines continued to operate without receiving the Government premium for any part of their output, and only 7 percent of the total "mine" value of the zinc concentrates (calculated for all concentrates upon the basis of the average grade and value reported for New York, Tennessee, and Virginia concentrates) represented premiums for overquota production. The ability of the zinc mines in the Eastern States to continue to produce zinc at comparatively low cost under war conditions indicates that their importance as a dependable domestic source of zinc will be enhanced in the postwar period. The lead output in 1944 came from New York and Virginia; the quantity produced in New York declined sharply, along with the decline in

zinc production, and that produced in Virginia increased materially. Copper output increased in Tennessee, Vermont, and Virginia and decreased in Pennsylvania and North Carolina. In North Carolina the Fontana and Hazel Creek copper mines were closed in January and October, respectively, and the State had no output of copper in November and December. War-inspired activity in prospecting and new development diminished as reserve stocks of copper and zinc were built up. The Bureau of Mines and Geological Survey continued to investigate sources of strategic and critical minerals; the work done on copper, lead, and zinc included exploratory diamond drilling and geophysical surveys in certain areas, scattered field examinations, and tests of ore-treatment methods.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported, except that of zinc in New Jersey, has been calculated at the prices in the following table. The value of the New Jersey output is the total value of the zinc recoverable as metal and oxide after freight, haulage, smelting, and manufacturing charges are added.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ⁴	Zinc ⁵
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063
1941.....	35.00	4.711+	.118	.057	.076
1942.....	35.00	4.711+	.121	.067	.093
1943.....	35.00	4.711+	.130	.075	.108
1944.....	35.00	4.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Co. for overquota production.

⁴ \$0.7111111.

Annual figures for the 5 years ended with 1944 are given in the table that follows. The figures for tonnage of ore sold or treated do not include magnetite ore containing pyrite and chalcopyrite, from which copper, gold, and silver were recovered as byproducts.

Mine production of gold, silver, copper, lead, and zinc in the Eastern States, 1940-44, in terms of recovered metals

Year	Mines producing		Ore sold or treated (short tons) ¹	Gold (lode and placer) ²		Silver (lode and placer) ³	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1940.....	40	18	3,674,815	18,456	\$645,960	102,825	\$73,120
1941.....	43	14	3,780,397	21,982	769,370	106,051	75,414
1942.....	36	17	4,130,226	14,699	514,465	105,307	74,885
1943.....	29	3	4,211,961	2,878	100,730	128,129	91,114
1944.....	26	2	4,202,461	2,595	90,825	124,006	88,182

¹ Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.

² Includes placer gold as follows: 1940, 452 ounces; 1941, 203 ounces; 1942, 69 ounces; 1943, 12 ounces; 1944, 5 ounces.

³ Placer silver did not exceed 30 ounces in any year during the 3-year period ended with 1942, and none was produced in 1943 and 1944.

Mine production of gold, silver, copper, lead, and zinc in the Eastern States, 1940-44, in terms of recovered metals—Continued

Year	Copper		Lead		Zinc		Total value
	Pounds	Value	Short tons	Value	Short tons	Value	
1940.....	25,490,000	\$2,880,370	4,831	\$483,100	178,815	\$24,135,445	\$28,217,995

Gold.—Most of the gold produced from mines in the Eastern States in 1944 was recovered as a byproduct from magnetite-pyrite-chalcopryrite ore from the Cornwall mine in Lebanon County, Pa.; the gold from this mine was contained in copper concentrates shipped to the Phelps Dodge smelting and electrolytic-refining plant at Laurel Hill, N. Y. A little gold was recovered from copper-iron ore from the Tennessee Copper Co. mines in Polk County, Tenn., and the Fontana mine in Swain County, N. C.; from copper ore from the Elizabeth mine in Orange County, Vt., and the Hazel Creek mine near Proctor, N. C.; and from zinc-lead ore from the Valzinco mine in Spotsylvania County, Va. About 5 ounces of gold were recovered from placer mines near Dahlonega, Ga. The estimated output of gold in the Southern Appalachian States from 1799 to 1944 is recorded as follows:

Mine production of gold in the Southern Appalachian States, 1799-1944

State	Period	Fine ounces	Value	State	Period	Fine ounces	Value
Alabama.....	1830-1944	49,489	\$1,198,775	South Carolina..	1829-1944	318,801	\$7,562,125
Georgia.....	1830-1944	870,526	18,064,257	Tennessee.....	1831-1944	20,722	472,900
Maryland.....	(1) -1944	6,102	163,940	Virginia.....	1828-1944	167,546	3,577,089
North Carolina..	1799-1944	1,164,588	24,327,843	Total.....	1799-1944	2,597,774	55,386,929

¹ Year of first production not recorded.

Silver.—The mine output of silver in the Eastern States in 1944 comprised 67,192 ounces recovered from copper and copper-iron ore from North Carolina, Tennessee, Vermont, and Virginia; 43,269 ounces from zinc-lead ore from New York and Virginia; and 13,545 ounces from magnetite-pyrite-chalcopryrite ore from Pennsylvania.

Copper.—Mine production of copper in the Eastern States was maintained at a slightly higher average monthly rate in 1944 than in 1943. The Fontana copper mine in Swain County, N. C., a steady producer since 1926, was closed January 31, 1944, but the loss in output from this mine was more than offset by steady production throughout the year from the old Elizabeth mine of the Vermont Copper Co. at South Strafford, Vt., which was reopened in September 1943; also, the old Toncrae copper mine in Floyd County, Va., was reopened in 1944 and shipped 1,926 tons of crude ore averaging about 7 percent copper. The Hazel Creek copper-[zinc] mine near Proctor, Swain County, N. C., was operated on a small scale from January through October and then closed, as the property was taken over

by the Tennessee Valley Authority for park purposes. Copper output from the Tennessee Copper Co. mines in Polk County, Tenn., principal producer in the Eastern States, was a little larger than in 1943; but that from the Cornwall iron (magnetite-pyrite-chalcopyrite) mine in Lebanon County, Pa., second-largest producer, decreased. In the following table by States the combined output of North Carolina, Pennsylvania, and Tennessee is shown under Tennessee to avoid disclosing output of individual mines.

Lead.—The mine output of lead in the Eastern States in 1944 was derived from zinc-iron-lead sulfide ore from the Balmat mine in New York and zinc-lead sulfide ore from the Austinville and Valzinco mines in Virginia; the quantity produced was 6,266 tons compared with 4,843 tons in 1943. The output in 1943 included 200 tons from Tennessee, most of which was recovered from lead carbonate ore from the Embree mine.

Zinc.—The mine output of 176,327 tons of zinc in 1944 was the lowest for the Eastern States in any year since 1938 and compares with 199,233 tons in 1943. The ore reserves were reported ample to maintain a production rate comparable with that in 1943 had sufficient manpower been available. In some of the large mines fully equipped headings in good ore were worked only part time owing to labor shortage. Large-scale mechanized operation of a recently developed open-pit mine in Tennessee prevented a material decline in output in that State. Zinc production in New Jersey decreased from 92,864 tons in 1943 to 80,288 tons in 1944, that in New York from 46,000 to 35,541 tons, and that in Tennessee from 41,766 to 40,831 tons; production in Virginia increased from 18,603 to 19,667 tons. The principal producing mines in all four States were the same as in 1943, but a few small producers that were active in 1943 did not operate in 1944. The Valzinco zinc-lead mine in Spotsylvania County, Va., which was reopened in 1942 and operated throughout 1943 and 1944, was closed in January 1945.

MINE PRODUCTION BY STATES

Mine production of gold, silver, copper, lead, and zinc in the Eastern States in 1944, by States, in terms of recovered metals

State	Mines producing		Ore (short tons)	Gold		Silver (all lode)	
				Fine ounces		Fine ounces	Total value

See footnote preceding page.

* Estimated smelting value of recoverable zinc content of ore after freight, haulage, smelting, and manufacturing charges are added.

† North Carolina and Pennsylvania included under Tennessee; Bureau of Mines not at liberty to publish these figures.

‡ Includes value of copper, which is included under Tennessee.

§ Includes also value of copper from North Carolina and Pennsylvania.

MINING INDUSTRY

Although no new war projects for expanding mine production of copper, lead, and zinc were undertaken in the Eastern States during 1944, emphasis continued on the need for maintaining maximum output from established operations consistent with proper utilization of the limited manpower available for war-essential industries. The sharp decline in lead stocks in the latter part of the year caused the War Production Board to request operators of lead mines to increase production, but this action did not materially affect mining in the Eastern States, as the bulk of the lead output in recent years has come from mines producing mostly zinc. Little manpower was available for underground development other than that required to extract currently mined ore. In Tennessee a fully mechanized open-pit mine, developed and equipped in 1943 and operated at a high rate throughout 1944, aided in maintaining zinc production. Diamond and churn drilling on extensions of ore bodies continued at approximately normal rates at most of the base-metal mines. The Bureau of Mines made geophysical surveys in the copper district in Orange County, Va., and the zinc-lead area at Paytes, Va., and did exploratory drilling on zinc-lead properties at Warren, N. H., and Paytes, Va., and on zinc properties in the Friedensville district in Pennsylvania and the New Hazewell-Powell River, Embreeville, and Eve's Mill areas in Tennessee. The wartime shut-down of the gold mines continued throughout 1944. The quantity of the various types of ore mined in the Eastern States is shown in the table that follows.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in the Eastern States in 1944, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (short tons)	Zinc (short tons)
Copper ore.....	1, 132, 178	343	67, 192	129, 784, 000	-----	(¹)
Magnetite-pyrite-chalcopyrite ore.....	(²)	2, 115	13, 545	(¹)	-----	-----
Zinc ore.....	2, 238, 144	-----	-----	-----	-----	128, 822
Zinc-lead ore.....	832, 139	132	43, 269	314, 000	6, 266	46, 505
Total, lode mines.....	4, 202, 461	2, 590	124, 006	30, 098, 000	6, 266	176, 327
Total, placer.....	-----	5	-----	-----	-----	-----
	4, 202, 461	2, 595	124, 006	30, 098, 000	6, 266	176, 327
Total, 1943.....	4, 211, 961	2, 878	128, 129	28, 490, 000	4, 843	199, 233

¹ Copper from magnetite-pyrite-chalcopyrite ore included with that from copper ore.

² Zinc from copper ore included with that from zinc-lead ore; Bureau of Mines not at liberty to publish separate figures.

³ Bureau of Mines not at liberty to publish separate figures for ore and copper.

⁴ Excludes magnetite-pyrite-chalcopyrite ore from Pennsylvania.

METALLURGIC INDUSTRY

No important changes were reported in metallurgical practice in copper, zinc, and zinc-lead ore-reduction mills in the Eastern States in 1944. The methods of treatment used and other operating details, including tonnage and grade of concentrates produced at some of the mills, are given in the Review by States that follows. Most of the concentrates are shipped to smelters operated by the companies that own the mines. No amalgamation or cyanidation mills were operated during the year. Five ounces of gold were recovered from placer mines by hand methods. Direct-smelting ore (142,473 tons) yielded 60 ounces of recoverable gold and 16,269 ounces of silver in 1944, and concentrates smelted (88,473 tons) yielded 2,530 ounces of gold and 107,737 ounces of silver; the figures for ore and concentrates do not include material containing no recoverable gold or silver. The total for direct-smelting ore was 143,622 tons and for concentrates (including low-grade concentrates shipped to oxide plants) 685,010 tons.

REVIEW BY STATES

GEORGIA

Individuals recovered 5 ounces of gold from scattered placer mines in Dawson and Lumpkin Counties in 1944. The gold was contained in small lots of retorts and grains sold to J. S. Speer, of Dahlonega, who combined the lots for shipment to the Philadelphia Mint.

NEW JERSEY

The output of crude zinc ore in New Jersey in 1944 was 543,007 tons yielding 80,288 tons of recoverable zinc as metal or in oxide compared with 602,646 and 92,864 tons, respectively, in 1943. The producing mines in both years were the Mine Hill at Franklin and the Sterling Hill at Ogdensburg, Sussex County. The commercial ore minerals comprise chiefly franklinite (a zinc-iron-manganese mineral) and willemite (zinc silicate) but also include zincite (red oxide of zinc). Each mine is equipped with a mill. In the reduction of the

ore the franklinite is removed from the crushed ore by magnetic separators, and the willemite and zincite are concentrated on jigs and tables. The concentrates are shipped to smelting and manufacturing plants at Palmerton, Pa. The franklinite is used in the manufacture of zinc oxide and spiegeleisen, and the willemite-zincite concentrate is smelted to produce high-grade slab zinc.

The value of the New Jersey output of zinc given in the table of this chapter under the heading Mine Production by States is the combined value of the zinc recoverable in both metal and oxide after freight, haulage, smelting, and manufacturing charges are added.

New Jersey has a few deposits of copper ore, but none has been worked for many years. Copper and lead smelters and refineries at Carteret and Perth Amboy treat ores, scrap, byproducts, and bullion from various States and foreign countries.

NEW YORK

New York has been a steady annual producer of zinc since 1915, of lead since 1930, and of silver since 1934. Lead and zinc were produced in some of the earlier years, and a little gold was reported recovered in experimental testing of black sands near Croghan, Lewis County, in 1909. No mine output of copper in the State has been recorded; the first complete mine canvass covered 1907. The silver, lead, and zinc are mined in a small area in St. Lawrence County east and southeast of Gouverneur. Most of the output in 1944, as in other recent years, was produced by the Balmat and Edwards mines of the St. Joseph Lead Co. In response to the need for expanding domestic mine output of zinc for war purposes, the company operated the mines at high production rates from 1941 to 1943, inclusive, and in 1943 New York ranked seventh among the States of the Union in zinc production. Operating rates averaged lower in 1944, and the State output of recoverable zinc dropped to 35,541 tons from 46,000 tons in 1943. The Balmat ore contains zinc, iron, and lead sulfides, and some silver is associated with the lead; it is mined through a 2,655-foot 40° inclined shaft (vertical depth, about 1,300 feet) and treated in the 1,200-ton selective flotation plant at the mine. The mill feed in 1944 totaled 303,451 tons; it yielded 2,776 tons of lead concentrates containing 60.46 percent lead and 11.7 ounces of silver to the ton, 49,322 tons of zinc concentrates containing 56.06 percent zinc, and 60,519 tons of pyrite concentrates containing 40.70 percent iron and 48.90 percent sulfur. The Edwards mine was operated through a vertical shaft 1,560 feet deep and an underground shaft (inclined 42° from horizontal) 1,226 feet to the mine workings. Ore treated totaled 101,739 tons yielding 18,005 tons of zinc concentrates containing 59.22 percent zinc. The zinc concentrates from both mills were shipped to the company smelter at Joseph-town, Pa.; the lead concentrates from the Balmat mill were shipped to the company Herculanum (Mo.) smelter. The pyrite concentrates were sold to sulfuric acid plants. The Universal Exploration Co. continued to operate its Hyatt mine and 200-ton flotation mill near Emeryville. The mine shaft is 450 feet deep. Development done in 1944 totaled 900 feet of drifts and 15,490 feet of diamond drilling. The concentrates were shipped to the Donora (Pa.) smelter.

There are no zinc or lead smelters in New York. The Phelps Dodge Refining Corporation has a custom copper smelter and an electrolytic

refinery at Laurel Hill which treat copper ore, matte, bullion, and copper-bearing scrap material.

NORTH CAROLINA

The only output of gold and silver in North Carolina in 1944 was that recovered as a byproduct of the mining of copper-iron and copper ores. The Condor (old Howie) mine near Waxhaw in Union County—principal producer of gold in the State in the years immediately preceding the wartime shut-down of the gold mines in 1942—was idle throughout 1943 and 1944. The State has produced no recoverable lead since 1938 and no zinc since 1913. The copper output in 1944 was much less than in 1943. The Fontana copper mine in Swain County, a steady producer since 1926, was closed January 31, 1944, and is not expected to reopen, as the proximity of the water level of the Fontana Dam on Little Tennessee River to the mine shaft will make it unsafe to operate the mine. The Hazel Creek copper-[zinc] mine and 25-ton flotation mill of the North Carolina Mining Co. near Proctor in Swain County were operated on a small scale from January through October and then closed, as the property was taken over by the Tennessee Valley Authority for park purposes. About 80 tons of 46-percent zinc concentrates containing some copper were produced in the mill but were re-treated to recover only the copper when the property was being cleaned up in preparation for abandonment. Seven tons of copper ore were shipped from the Bear Creek mines in Chatham County to the U. S. Metals Refining Co. smelter at Carteret, N. J.

PENNSYLVANIA

The Pennsylvania output of gold, silver, and copper was derived from magnetite-pyrite-chalcopyrite ore from the Cornwall mine of the Bethlehem Steel Co. in Lebanon County. The mine is developed by an open pit and three inclined shafts 1,700 feet deep. The ore is crushed to about 1-inch size at the shafts in Cornwall and shipped in standard hopper-bottom railroad cars to the combined magnetic concentration and flotation mill at Lebanon. The magnetic concentration equipment has a daily capacity of 6,500 tons and the flotation equipment 2,800 tons. Other equipment includes a 2,400-ton sintering plant which handles part of the magnetic concentrates; the rest is shipped to another plant at Bethlehem. The flotation equipment treats tailings from the magnetic separators for the recovery of copper concentrates, which contain most of the gold and silver, and pyrite concentrates, which contain cobalt. The copper concentrates are shipped to the Phelps Dodge smelter and electrolytic refinery at Laurel Hill, N. Y., and the pyrite concentrates to plants outside the State for recovery of sulfur (as sulfuric acid) and cobalt; the final pyrite residue is sintered and shipped to an iron and steel plant.

The zinc mines in Pennsylvania have been idle for many years. Exploratory drilling by the Bureau of Mines on the Correll zinc property in the Friedensville district, Lehigh County, was completed in January 1944. Zinc smelters at Donora, Langeloth, Josephstown, and Palmerton treat the largest part of the zinc concentrates produced in the Eastern States, as well as large tonnages from the

Central States and foreign countries. There is a roasting plant for concentrates at New Castle and an electrogalvanizing plant for sheets at Johnstown that uses roasted zinc concentrates.

SOUTH CAROLINA

Mines in South Carolina yielded no gold, silver, or copper in 1944; the output in 1943—all from the Terry mine near Smyrna, York County—was 147 fine ounces of gold, 135 fine ounces of silver, and 1,000 pounds of copper. The Haile mine in Lancaster County, equipped with a 400-ton cyanide mill, was the principal producer of gold in South Carolina and in the Eastern States in each year of the 3-year period ended in 1942. The mine will presumably remain closed until Gold Mining Limitation Order L-208 is canceled and conditions are again favorable for gold mining.

TENNESSEE

Production of recoverable zinc in Tennessee was 40,831 tons in 1944 compared with 41,766 tons in 1943 and the peak of 43,971 tons in 1942. The decreases in the past 2 years were caused by shortage of labor in the mines, as ore reserves and mill capacities were adequate for production equal to that in 1942. No lead was produced in the State in 1944 and only 200 tons in 1943. The output of gold, silver, and copper did not vary greatly from 1943. The gold and silver were recovered as byproducts from copper-iron-zinc ore from the mines of the Tennessee Copper Co. at Ducktown, Polk County. In 1944 the company continued to operate the Burra Burra, Eureka, Boyd, and Calloway mines and the London and Isabella flotation mills. The 1,200-foot Gordon shaft was reopened during the year, and the Mary mine was unwatered. The average depth of the four ore-hoisting shafts is about 1,500 feet. Development done in 1944 totaled 553 feet of shaft, 15,727 feet of drifts, and 39,061 feet of diamond drilling. The ore contains sulfides of iron, copper, and zinc. The iron concentrates produced in the mills are roasted to release the sulfur for use in making sulfuric acid in company plants at Isabella and Copperhill; the oxidized calcines from the roasters are sintered and sold to iron and steel producers. The zinc concentrates are shipped to the Donora (Pa.) smelter. The copper concentrates are smelted in a reverberatory furnace at the company Copperhill smelter without preliminary roasting. The smelter has two stand-by blast furnaces, one of which was operated on crude ore in 1944 to boost production of sulfuric acid. The matte from the reverberatory and blast furnaces was treated in a converter. A small tonnage of copper concentrates was treated directly in the converter for gas and temperature control. Most of the blister copper from the converter was cast into pigs and shipped to an electrolytic refinery on the Atlantic seaboard, where some gold and silver were recovered as byproducts. Shot copper was produced for use in the company copper sulfate plant at Copperhill.

The bulk of the zinc output of Tennessee in 1944 continued to come from the Mascot-New Market-Jefferson City district. The American Zinc, Lead & Smelting Co. operated the Mascot No. 2 mine in Knox County and the Grasselli, Shallow Ore, Jarnagin, and Mossy Creek

in Jefferson County. The Mascot is opened by a 520-foot shaft and an inclined shaft from the 520-foot level to the maximum depth of 850 feet; it also has an auxiliary manway shaft and a ventilating shaft. The Grasselli has one operating shaft and an auxiliary manway shaft and is 350 feet deep. The Jarnagin has one operating shaft 280 feet deep, with an auxiliary manway shaft. The Mossy Creek is opened by a 249-foot incline shaft. The Shallow Ore had one open pit 750 feet long, 500 feet wide, and 45 feet deep at the beginning of the year; stripping to open another pit was done during the year, and the first pit was worked to a depth of about 80 feet. All the mines are fully mechanized. Slushing is the principal method of underground loading, and power shovels, bulldozers, and 19-ton caterpillar trucks are used in loading and haulage in the open pits. Development done at the four underground mines in 1944 totaled 5,427 feet of drifts and raises, 32,462 feet of diamond drilling, and 21,101 feet of churn drilling. An additional 1,607 feet of churn drilling was done at the Shallow Ore mine. The crude ore from all five mines was treated in the company mill at the Mascot No. 2 mine. The ore from the four mines in Jefferson County was transported to the mill over the Southern Railway. The mill is equipped with a differential-density cone unit, jigs, and flotation machines and has a capacity of 4,000 tons daily. It treated 1,339,862 tons of crude ore in 1944, and its total output of zinc concentrates was 55,690 tons—a 6-percent increase over 1943. The increase was made possible by greatly expanding production from the Shallow Ore open-pit mine, as output from the underground mines was reduced by labor shortage. The annual company report to stockholders contains the following data on prospecting on optioned properties and ore reserves: Prospecting on outside properties in Knox County consisted of 3,565 feet of diamond drilling; in Jefferson County, 23,417 feet of diamond and churn drilling; and in Hamblen County, 3,000 feet of diamond drilling. Drilling results for the year were encouraging. A new mine was indicated on one property in Jefferson County. Drilling results on this property since the end of the year have materially extended indicated reserves, and if labor is available development preparatory to production will be started during the third quarter of 1945. Ore reserves at the end of 1944 on properties owned or under lease (not including any of the new ore indicated on properties under option or under management contract or the Shallow Ore mine) show an increase of approximately 2,000 tons of concentrates above the reserves at the end of 1943.

The Universal Exploration Co. group of mines and 800-ton flotation mill at Jefferson City were operated at less than capacity most of 1944 owing to inability to obtain enough workers to man the equipment at all working faces in the mine; consequently, the output of concentrates was less than in 1943. The average grade of the concentrates shipped in 1944 was 64.29 percent zinc. The mine is worked through two shafts 180 and 240 feet deep. Development done in 1944 totaled 300 feet of drifts, 27,961 feet of diamond drilling, and 11,030 feet of churn drilling. New incline and slusher hoists were installed underground. During the year the company began developing the Straight Creek mine in the New Tazewell area in Claiborne County. An old 800-foot tunnel was cleaned out and enlarged, surface build-

ings were constructed, and air compressors, incline hoists, slusher hoists, and pumps were installed. An electric power line was run to the mine. Sinking of an underground incline and other development were begun in December. The Lacy-Butler Co. shipped 54 tons of washed carbonate ore from the Cooper mine at Jefferson City to the American Agricultural Chemical Co. at Carteret, N. J. The Bunche's Hollow mine and 100-ton flotation mill of the Imperial Mining Co. near Goin, Claiborne County, were idle throughout 1944. The New Prospect mine at Lead Mine Bend, operated on a small scale in 1942 and 1943, was closed in January 1944. The Bureau of Mines did prospect diamond drilling on the Idol, Dalton, Stiner, and Tennessee Valley Authority properties in the New Tazewell-Powell River area and the Eve's Mill property in Monroe County. The Embree group of mines in Washington and Unicoi Counties made no output of zinc or lead in 1944. The exploratory diamond-drilling project of the Bureau of Mines on this property was suspended in January, but the Tennessee Zinc Co. did additional churn drilling during the year. The Hoover mine and small gravity-concentration mill in Cannon County east of Murfreesboro were operated intermittently, as the water supply for the mill was low during the summer.

VERMONT

The Vermont Copper Co. operated the Elizabeth mine and 500-ton flotation mill in Orange County throughout 1944. The mine was worked through a 1,200-foot adit, an underground 30° inclined shaft which was 925 feet long at the end of the year, and four main levels opening up the vein, which has a strike length of 1,000 feet. The ore minerals are chalcopyrite and pyrrhotite, carrying some silver and a little gold. The broken ore is hauled by underground tram to loading chutes on the adit at the top of the underground shaft and from there to the mill by an electric locomotive in Granby-type ore cars of 5-ton capacity. Ore milled in 1944 totaled 91,289 tons averaging 2.26 percent copper; it yielded 8,824 tons of concentrates containing 21.60 percent copper and 2.50 ounces of silver and 0.015 ounce of gold to the ton. The concentrates were shipped to the Phelps Dodge smelter at Laurel Hill, N. Y. The Bureau of Mines made a geophysical survey of the Orange County copper district during the year.

VIRGINIA

No gold mines were operated in Virginia in 1944, but some gold, silver, and copper were recovered from zinc-lead ore, and a little silver was derived from copper ore. The Toncræ copper mine in Floyd County was reopened by the Toncræ Mining Co. and began shipping ore to the U. S. Metals Refining Co. at Carteret, N. J., in April. The mine had been idle for many years and was among the properties drilled by the Bureau of Mines in its expanded exploratory program begun in 1942 to stimulate output of strategic and critical war minerals. Ore shipped in 1944 totaled 1,926 tons averaging about 7 percent copper; in addition, 2,100 tons of lower-grade ore was mined and stock-piled for treatment later by leaching. The output of recoverable lead in Virginia increased from 2,288 tons in 1943 to 4,622

tons in 1944, and zinc from 18,603 to 19,667 tons. The Austinville zinc-lead mine in Wythe County, which has produced the bulk of the Virginia output of zinc and lead since 1927, was operated continuously in 1944; the ore was treated in the 2,000-ton selective flotation mill at the mine. The output of both zinc and lead concentrates was larger than in 1943. The Valzinco zinc-lead mine and 100-ton flotation mill near Paytes in Spotsylvania County were operated throughout 1944 but were closed in January 1945. The mine was reopened in 1942 by Panaminas, Inc., subsidiary of Ventures, Ltd., and had been in production since September of that year. The mill products in 1944 were zinc concentrates and zinc-lead concentrates, both containing some gold, silver, and copper. The zinc concentrates were shipped to the Langeloth (Pa.) smelter and the zinc-lead concentrates to the International (Utah) lead smelter and slag-fuming plant. The drilling project of the Bureau of Mines on this property was completed in January, but experimental geophysical prospecting was done on this and other adjacent properties late in the year.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN IDAHO

(MINE REPORT)

SUMMARY

The total value of gold, silver, copper, lead, and zinc produced by Idaho mines was \$42,591,137 in 1944 compared with \$43,199,910 in 1943—a 1-percent decrease (see fig. 1). The value of the gold output was \$875,280 (2 percent of the State total), silver \$7,062,481 (nearly 17 percent), copper \$455,760 (1 percent), lead \$13,364,800 (31 percent), and zinc \$20,832,816 (49 percent). The quantity and value of each metal, except zinc, produced were less than in 1943. Compared with 1943, gold production decreased 19 percent, silver 15, copper 27, and lead 13 percent; zinc production increased 5 percent. In 1944 Idaho was the largest producer of silver, antimony, and tungsten in the United States and ranked second in lead and zinc; the output of zinc was the greatest in any year in the history of the State.

Production of copper, lead, and zinc in Idaho in 1944 was affected by the following factors: An acute shortage of labor, which was more serious than in 1943; the marked increase in output of zinc from the Bunker Hill & Sullivan zinc slag-fuming plant at Bradley and the Hecla zinc-lead tailing plant at Osburn; the large production of lead-silver ore from the Chester vein and the Silver Syndicate fault zone in the Coeur d'Alene region by the Sunshine Mining Co.; the notable decrease in output of silver, lead, and zinc from the Hecla mine at Burke, resulting from exhaustion of known commercial ore; the suspension (temporarily) in March of mining silver-copper-antimony ore from the Sunshine mine near Kellogg; and the marked decrease in output of silver-copper-antimony ore from the Mineral Point (Coeur d'Alene Mines Corp.) mine near Osburn.

Premium payments for overquota production of copper, lead, and zinc were in force throughout 1944. Considerable assistance was given to mine operators in Idaho in 1944 by the Grazing Service and Forest Service through the building of access roads to various properties. Most of the roads approved for construction were to zinc-lead and lead properties in Blaine, Butte, Camas, Clark, Lemhi, and Shoshone Counties. The Federal Bureau of Mines, in cooperation with the Federal Geological Survey, did much work in 1944 exploring and

testing various properties throughout the State. Most of this work was drilling test holes at the Blackbird cobalt-copper deposit in Lemhi County, the Pine Creek zinc-lead area of the Coeur d'Alene region, the mica-beryl deposits in Latah County, the Clark Fork lead-silver district in Bonner County, and the fluorspar deposits on Camas Creek near Meyers Cove in Lemhi County.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063

¹ A floating washing plant supplied with gravel by a dragline excavator is called a "dragline floating dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

Gold.—The output of recoverable gold in Idaho was 25,008 fine ounces in 1944, the smallest output since 1931 and 19 percent less than in 1943. This decrease resulted principally from a marked decline in output of gold from the Boise-Rochester-Monarch (Talache Mines, Inc.) property at Atlanta, which had been the largest producer of gold in Idaho since 1940. The yield of gold from lode mines decreased from 50,553 ounces in 1943 to 24,872 ounces in 1944 and that from placers from 255 to 136 ounces. The output of gold from lode mines in 1942 was 50,440 ounces and that from placers 44,580 ounces. The output of gold from placers in 1944 was the smallest since 1862, the year before placer gold was first mined in the State. About 53 percent of the State total gold in 1944 came from siliceous gold ore, 43 percent from zinc-lead ore, and nearly all the remainder from lead ore, copper ore, silver ore, and placers. In 1944 more than 79 percent of the State gold output came from three lode mines—in the Yellow Pine, Warm Springs, and Middle Boise (Atlanta) districts.

The Bradley Mining Co., operating the Yellow Pine mine at Stibnite, was the largest gold producer in Idaho in 1944; it was followed, in order, by the Triumph mine near Ketchum and the Boise-Rochester-Monarch property at Atlanta.

Silver.—The output of recoverable silver in Idaho was 9,931,614 fine ounces in 1944—15 percent less than in 1943. The loss was attributed largely to suspension in March of the mining of silver-copper-antimony ore from the Sunshine vein by the Sunshine Mining Co.; however, a greater decrease was prevented through the large output of lead-silver ore made from the Chester vein and the Silver Syndicate fault zone near Kellogg by the Sunshine Mining Co. Large decreases in silver output were reported also by the Mineral Point, Bunker Hill & Sullivan, Hecla, Polaris, Morning, Triumph, Page, Tamarack, Yellow Pine, Gold Hunter, and Sherman properties. The Coeur d'Alene region produced 87 percent of the State total silver in 1944; the remainder came largely from the Warm Springs, Bayhorse, Yellow Pine, Deadwood Basin, Blue Wing, Clark Fork, and South Mountain districts. Of the State total silver, zinc-lead ore and old tailings yielded 43 percent, lead ore 32 percent, silver ore 22 percent, and gold ore, zinc ore, and zinc slag nearly all the remainder. The recovery of silver from silver ore decreased 2,379,088 ounces (mainly at the Sun-

shine and Mineral Point mines) and from zinc-lead ore 677,979 ounces, but that from lead ore increased 1,359,947 ounces owing to the yield from the Chester vein and the Silver Syndicate fault zone.

Ten mines—the Sunshine, Polaris, Bunker Hill & Sullivan, Triumph, Osborn tailing plant, Page, Silver Dollar, Morning, Mineral Point, and Silver Syndicate—produced 76 percent of the silver output of the State in 1944. All these except the Triumph are in the Coeur d'Alene region.

Copper.—The output of recoverable copper in Idaho in 1944 was 3,376,000 pounds—27 percent less than in 1943. The loss was due mainly to the decreased output of silver-copper-antimony ore from the Mineral Point and Sunshine mines in the Coeur d'Alene region. About 76 percent of the State copper output in 1944 came from zinc-lead ore, silver ore, and lead ore from mines in the Coeur d'Alene region; the remainder came largely from zinc-lead ore in the Warm Springs district, copper ore in the Alder Creek and Seven Devils districts, and zinc ore in the South Mountain district.

FIGURE 1.—Value of mine production of gold, silver, lead, and zinc and total value of gold, silver, copper, lead, and zinc in Idaho, 1870–1944. The value of copper has been less than \$2,000,000 annually, except in a few years.

The Mineral Point mine remained the largest producer of copper in Idaho, but its output in 1944 was 67 percent less than in 1943. It was followed by the Sunshine, Polaris, Triumph, Osburn tailing plant, and Bunker Hill & Sullivan properties.

Lead.—The output of recoverable lead in Idaho was 167,060,000 pounds in 1944, the smallest output since 1935 and a 13-percent decline from 1943. The total decrease in lead output at the Bunker Hill & Sullivan, Morning, and Hecla mines was 39,933,588 pounds, which more than offset substantial increases at the Osburn tailing dump, Sunshine, Polaris, and Monitor properties and the Sweeny tailing dump. About 92 percent of the State total lead came from the Coeur d'Alene region; most of the remainder was produced in the Warm Springs, Bayhorse, Lava Creek, Deadwood Basin, Moyie Yahk, Texas, and Clark Fork districts. Zinc-lead ore and old tailings (2,330,974 tons) from the Coeur d'Alene region yielded 73 percent of the State total lead; and lead ore, chiefly from the Coeur d'Alene region, yielded nearly 17 percent; the remainder came largely from

zinc-lead ore in the Warm Springs district and from zinc slag and silver ore in the Coeur d'Alene region. Lead recovered from zinc-lead ore and old tailings decreased 32,501,118 pounds; but lead from lead ore increased 3,236,449 pounds, that from zinc ore and slag 2,407,360 pounds, and that from silver ore 1,225,231 pounds.

In 1944 the combined lead output of the four largest producers—the Bunker Hill & Sullivan, Morning, Star, and Page—was 75,564,904 pounds or more than 45 percent of the State total. In 1943 the combined lead output of these properties and the Hecla mine was 126,092,988 pounds. Other important producers in 1944 were the Osburn tailing plant, Tamarack, Sherman, Triumph, Sunshine (Chester vein), Polaris (Chester vein), Hecla, Sweeny tailing dump, Frisco, Monitor, and Clayton properties.

Zinc.—The output of recoverable zinc in Idaho was 182,744,000 pounds in 1944—the largest output in any year in the history of the State and a 5-percent increase over 1943. Idaho as a zinc-producing State moved from third place in 1943 to second in 1944, passing New Jersey but not yet overtaking Oklahoma. Marked increases in output of zinc at the Bunker Hill & Sullivan zinc slag-fuming plant, Osburn tailing plant, Monitor, Page, Little Pittsburg, Highland-Surprise, Nabob, and Douglas properties more than offset substantial decreases at the Morning, Hecla, Star, and Tamarack properties. More than 93 percent of the State total zinc in 1944 came from the Coeur d'Alene region and nearly all the remainder from the Warm Springs, South Mountain, Lava Creek, Deadwood Basin, Bayhorse, and Moyie Yahk districts. Zinc-lead ore and old tailings concentrated yielded 86 percent of the State total zinc, zinc slag fumed and zinc slag smelted 12 percent, and lead ore concentrated and zinc ore concentrated nearly all the remainder.

Eleven properties—the Star, Morning, Bunker Hill & Sullivan mine, Page, Osburn tailing plant, Bunker Hill smelter slag dump, Tamarack, Triumph, Bunker Hill & Sullivan zinc slag-fuming plant, Monitor, and Frisco—produced 80 percent of the State total zinc in 1944.

MINING INDUSTRY

In spite of a serious labor shortage throughout 1944, especially at the large zinc-lead properties in the Coeur d'Alene region, more ore, old tailings, and slag were mined and treated than in any year in the history of Idaho. However, the 19-percent gain over the total for 1943 resulted principally from an increased output of zinc-lead old tailings and zinc slag. The output of zinc-lead ore and old tailings (by far the chief output of the State) increased 31 percent, zinc ore and slag 191 percent, and lead ore nearly 7 percent; but dry siliceous ores decreased 31 percent. Nearly all the gold ore mined in Idaho in 1944 came from two properties—one in the Middle Boise (Atlanta) district and the other in the Yellow Pine district; 71 percent of the silver ore, 93 percent of the lead ore, 94 percent of the zinc ore and slag, and 92 percent of the zinc-lead ore and old tailings came from various properties in the Coeur d'Alene region; and 88 percent of the copper ore came from one mine in the Alder Creek (Mackay) district.

ORE CLASSIFICATION

Details on ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Idaho in 1944, with content in terms of recovered metals

Source	Mines producing	Ore	Gold	Silver	Copper	Lead	Zinc
		<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>
Dry and siliceous gold ore.....	14	256,640	13,270	136,063	6,752

Total, lode mines.....	* 112	3,271,038	24,872	9,931,583	3,376,000	167,060,000	182,744,000
Total, placers.....	20		136	31			
Total, 1944.....	132	3,271,038	25,008	9,931,614	3,376,000	167,060,000	182,744,000
	157	2,741,747	30,808	11,700,180	4,648,000	192,914,000	173,414,000

* Includes 115,281 tons of zinc slag.

* A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

METALLURGIC INDUSTRY

Of the 3,271,038 tons of ore produced in 1944 in Idaho, 3,140,182 tons (96 percent) were treated at concentration and fuming plants, 57,231 tons (nearly 3 percent) were shipped crude to smelters, and 73,625 tons (1 percent) were treated at amalgamation mills.

Concentration plants in 1944 treated 211,382 tons of gold ore, 156,947 tons of silver ore, 500 tons of copper ore, 250,079 tons of lead ore, 13,521 tons of zinc ore, and 2,520,578 tons of zinc-lead ore and old tailings. Although 76,664 tons of current hot zinc slag were fumed and 78,106 tons of old dump zinc slag were smelted and fumed

in 1944, only the dump slag and 37,175 tons of hot slag were credited directly to the fuming-plant operation; the remainder of the hot slag (39,489 tons) was credited to various producers of the ores and concentrates that contributed during the year to the slag-making material.

Ore treated at straight amalgamation mills in 1944 totaled 84 tons and that at combined amalgamation and concentration plants, 43,541 tons; none was treated at cyanidation plants.

The Bunker Hill & Sullivan Mining & Concentrating Co. operated its Bradley lead smelter and refinery at near capacity in 1944 on ore and concentrates, chiefly from mines and mills in the Coeur d'Alene region. The company also operated its antimony and bismuth plant, 1,700-ton flotation mill (including sink-and-float unit), 300-ton tailing-treatment plant for recovery of silver, iron, and lead from old jig tailings, and 450-ton zinc slag-fuming plant at Bradley. The slag-fuming plant yielded 23,458 dry tons of de-leaded zinc fume and 4,077 dry tons of lead fume. The electrolytic antimony plant (100-ton capacity) of the Sunshine Mining Co. near Kellogg was closed in March, when the Sunshine Mining Co. decided to concentrate all its available manpower on mining lead-silver ore from its Chester vein instead of mining silver-copper-antimony ore from its Sunshine vein. The Sullivan Mining Co. operated continuously at capacity its 100-ton electrolytic zinc plant near Bradley on zinc and zinc-lead concentrates and oxide zinc fume produced mainly from plants in the Coeur d'Alene region. During the year the Sullivan Mining Co. and the Metals Reserve Company stock-piled several thousand tons of zinc concentrates at Bradley. Antimony, tungsten, and antimony-iron-gold concentrates were produced throughout the year in the 800-ton flotation mill of the Bradley Mining Co. at Stibnite and tungsten concentrates and silver-copper-lead-iron concentrates in the Ima mill at Patterson. During the spring months of 1944 the Bradley Mining Co. remodeled an old building in Boise to house a leaching plant. Some of the tungsten concentrates produced at the company mill at Stibnite were hauled to this leaching plant, where muriatic acid was used to eliminate the apatite and calcite and caustic soda to eliminate the antimony from the concentrates; this additional treatment produced a 70-percent tungstic oxide concentrate, which was sold direct to the steel plants.

Mine production of metals in Idaho in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated	Gold	Silver	Copper	Lead	Zinc
	<i>Short tons</i>	<i>Fine ounces</i>	<i>Fine ounces</i>	<i>Pounds</i>	<i>Pounds</i>	<i>Pounds</i>

! Lava Creek district lies in both Blaine and Butte Counties.

ADAMS COUNTY

Leasing operations in 1944 at three properties near Cuprum in the Seven Devils district produced a total of 203 tons of carbonate copper ore; 153 tons came from the Arkansaw-Decorah group, 32 tons from the Helena claim, and 18 tons from the Lockwood group.

BLAINE COUNTY

Lava Creek district.—Hoyt Ray worked the Paymaster mine, 32 miles southwest of Arco, throughout the year and shipped 4,947 tons of zinc-lead ore to a custom flotation mill at Midvale, Utah, where it was separated into lead concentrates, zinc concentrates, and iron concentrates.

Little Wood River (Muldoon) district.—Leasing at the Eagle Bird mine in Garfield Canyon during the summer months of 1944 produced 162 tons of zinc-lead ore and 39 tons of oxide silver-lead ore. The remainder of the district output was principally 39 tons of zinc-lead ore and 19 tons of silver-lead ore produced from the Idaho Muldoon property.

Mineral Hill and Camas district.—In 1944 a total of 1,820 tons of ore and 511 tons of old tailings was shipped from five properties in the Mineral Hill and Camas district; 1,027 tons were siliceous gold ore shipped direct to a smelter from the Camas mine, 792 tons were zinc-lead ore produced from the Snoose mine and shipped to custom mills in Utah, and the remainder was largely silver old tailings (461 tons) from the Red Elephant property.

Sawtooth (Vienna) district.—A lessee worked the Vienna mine, 45 miles northwest of Ketchum, in 1944 and shipped 80 tons of high-silica gold-silver ore to a smelter in Utah.

Warm Springs district.—The principal output of the Warm Springs district in 1944 continued to be zinc-lead-silver ore from the Triumph-North Star-Independence groups near Ketchum operated by the Triumph Mining Co. The company operated the groups throughout the year and treated 52,060 tons of low-grade zinc-lead-silver ore in its 300-ton concentrator, recovering lead-silver concentrates and zinc-lead middlings. The middlings (13,449 tons) and 57,667 tons of higher-grade zinc-lead-silver ore were shipped to custom flotation mills at Bauer and Tooele, Utah, for treatment, and the lead-silver concentrates (2,893 tons) were shipped direct to a lead smelter. In addition, 888 tons of old tailings (silver) were shipped to a copper smelter. The rest of the district output comprised 798 tons of zinc-lead ore and 180 tons of oxide zinc ore produced from the Homestake mine near Ketchum, 474 tons of siliceous gold ore from the June Day mine, 200 tons of zinc ore from the Lucky Boy mine, and 74 tons of zinc-lead ore from the Blue Kitten claim.

BOISE COUNTY

Boise Basin district (Centerville, Placerville, Idaho City, Pioneerville, Quartzburg).—Mining operations (both lode and placer) in the gold district of Boise Basin have been negligible since October 1942 when the War Production Board promulgated the gold-mine closing order. The principal output from lode mines in the district in 1944 was 70 tons of old mill cleanings (containing chiefly gold) shipped from the Gold Hill & Iowa mill, 62 tons of high-grade gold-silver ore shipped

direct to a smelter from the Come-Back mine, and 60 tons of gold ore from the Juliana claim treated by amalgamation. The placer output of 65 ounces of gold and 17 ounces of silver resulted mainly from clean-ups around former dredging operations.

Summit Flat district.—All the output (24 tons) in the Summit Flat district in 1944 was high-grade gold ore produced from the Jessie, Rock Creek, and Viking properties and treated by amalgamation.

BONNER COUNTY

Clark Fork district (formerly part of Pend d'Oreille district).—The principal output in the Clark Fork district in 1944 was 4,714 tons of silver-lead ore from the Hope (Elsie K.) and Whitedelf properties near Clark Fork. Hope Silver-Lead Mines, Inc., operated its 150-ton flotation mill on silver-lead ore (2,843 tons) produced from the Hope mine until March 30, when milling operations ceased owing to an insufficient supply of ore, caused by a shortage of miners, to keep the mill running. In April the company began sinking a vertical shaft at the property so as to develop ore bodies at greater depth. The Whitedelf Mining & Developing Co. rehabilitated its mine and 50-ton mill late in 1943 after being closed for 2 years; in 1944 the company treated 1,858 tons of silver-lead ore by flotation. Nearly all the remainder of the district output was lead ore (32 tons) produced from the Laurence mine.

Lakeview district.—About 180 tons of silver ore (containing some lead and zinc) were produced from the Hewer (Idaho Lakeview) mine in 1944 and treated by flotation. The rest of the district output was 16 tons of zinc-lead-silver ore shipped direct to a smelter from the old Cement mine.

BOUNDARY COUNTY

Moyie Yahk district.—Mining and milling of gold-silver-lead-zinc ore at the Regal property, 14 miles northeast of Bonners Ferry, by Silver Crescent, Inc., were continuous throughout the year. The company reported that 9,421 tons of sulfide ore containing 980 ounces of gold, 13,200 ounces of silver, 14,000 pounds of copper, 423,000 pounds of lead, and 550,000 pounds of zinc were treated by flotation; zinc-lead concentrates and zinc concentrates were shipped to smelters at Bradley, Idaho.

Port Hill district.—The Idaho-Continental mine and mill were idle most of 1944, resulting in a marked decrease in the district production of silver and lead; however, the property was taken over late in the year by the Idaho-Continental Leasing Co., and 900 tons of lead ore were treated by flotation.

BUTTE COUNTY

Dome district.—In 1944 approximately 450 tons of old tailings (containing chiefly lead) from the Wilbert dump near Howe were treated by flotation.

Lava Creek district.—The Era Mining & Development Co. mined zinc-lead ore throughout the year at the Horn Silver mine, 20 miles southwest of Arco; a total of 8,034 tons of sulfide ore, averaging

0.03 ounce of gold and 1.97 ounces of silver to the ton, 0.20 percent copper, 3.48 percent lead, 6.23 percent zinc, and 6.50 percent iron was shipped to a custom flotation mill in Utah.

CAMAS COUNTY

Little Smoky and Carrietown district.—A lessee worked the waste dump of the Carrie Leonard property in 1944 and shipped 97 tons of zinc-lead-silver ore to a custom mill and 49 tons of silver ore to a smelter. Silver ore (78 tons) was shipped from the Stormy Galore mine.

CLARK COUNTY

The only output in Clark County in 1944, as in 1943, was lead ore produced from the Scott mine on Birch Creek. The Birch Creek Mining Co., Ltd., operated the mine continuously and shipped 586 tons of oxide lead ore to a smelter in Utah.

CUSTER COUNTY

Alder Creek district.—The Mackay Exploration Co. did considerable work in 1944 in rebuilding the flotation mill, installing machinery at the power plant, and constructing a 2¼-mile transmission line from the power plant to the mill at its Empire property near Mackay. Mining of copper ore at the mine was begun in July, and during the remainder of the year 2,330 tons of crude copper ore were shipped to the smelter at Garfield, Utah, and 500 tons of similar ore were treated in the company mill. The rest of the district output was mainly 252 tons of zinc-lead ore from the Horseshoe mine and 200 tons of lead ore from the Champion mine.

Alta (Little Fall Creek) district.—Most of the output in the Alta district in 1944 was 36 tons of sulfide zinc-lead ore and 17 tons of siliceous silver ore shipped from the Long Trail claim 14 miles northeast of Ketchum.

Bayhorse district.—Mining and milling of zinc-lead ore at the Clayton mine by Clayton Silver Mines continued throughout 1944. The company reported that 39,258 tons of ore, containing an average of 5.72 ounces of silver to the ton, 4.71 percent lead, and 1.58 percent zinc, were treated in its 120-ton flotation mill and yielded 2,644 tons of high-grade lead-silver concentrates and 645 tons of zinc concentrates. More lead-silver concentrates but less zinc concentrates were produced in 1944 than in 1943, resulting in a greater output of lead and silver and a substantial decline in zinc. Swigert Mines operated the Pacific claim of the Salmon River group near Challis most of the year and treated 6,585 tons of oxide lead-silver ore by gravity concentration. The remainder of the district output comprised 2,676 tons of oxide lead-silver ore produced from the South Butte and Red Bird properties, 200 tons of silver ore from the Hoosier claim, 72 tons of lead ore from the Twin Apex group, and 39 tons of high-grade silver-lead-copper ore from the Ramshorn mine.

Yankee Fork district.—Lessees continued in 1944 to work the Fourth of July claim near Sunbeam and shipped 21 tons of high-grade gold ore to a smelter. The rest of the district output was principally placer gold and silver recovered from gravel at the Horse Trail property.

ELMORE COUNTY

Middle Boise (Atlanta) district.—Mining and milling of gold ore at the Boise-Rochester-Monarch property by Talache Mines, Inc., continued from January 1 to November 1, when operations ceased owing to Government restrictions and a shortage of labor. The company reported that 43,541 tons of gold ore were treated in its 400-ton amalgamation and concentration mill in 1944 compared with 53,424 tons in 1943 and that 32 tons of rich gold ore were shipped direct to a smelter. In addition to gold and silver, the milling ore contains arsenic and tungsten, but none of these products were marketed in 1944. The output of placer gold in the district totaled only 2 ounces.

GEM COUNTY

West View district.—The Friday mine at Pearl was worked under lease by the Friday Mining Co. until April 30, when operations ceased owing to exhaustion of commercial ore. During the first 4 months of the year 104 tons of sulfide ore averaging 0.69 ounce of gold and 11.99 ounces of silver to the ton, 5.66 percent lead, and 5.81 percent zinc were shipped to a custom flotation mill in Utah, and 4 tons of high-grade gold ore were shipped direct to a smelter.

IDAHO COUNTY

Most of the mining districts in Idaho County are gold-producing areas (placer and lode), and since War Production Board Order L-208 closing gold mines was issued in October 1942 virtually all the mines in the districts have been idle. In 1944, a little placer gold was recovered from claims in the Camp Howard, Elk City, Florence and French Creek, Newsome, Simpson, and Warren districts, and a little lode gold and silver were produced from the Mammoth mine in the Dixie district; a lessee worked the Rusty Lode claim near Kooskia in the Lowell district and shipped 70 tons of zinc-lead ore to custom flotation mills in Utah.

LEMHI COUNTY

Blue Wing district.—Mining and milling of ore containing hübnerite, galena, tetrahedrite, and pyrite at the Ima property by the Ima Mines Corp. continued throughout the year. The company reported that 29,587 tons of ore were treated in 1944 in its 150-ton concentration plant; tungsten was recovered by gravity and flotation concentration, followed by magnetic separation, and silver, copper, and lead were recovered by bulk sulfide flotation. Lead-copper-silver concentrates (1,046 tons) were shipped to a smelter in Utah, and tungsten concentrates were sent to an eastern market.

Eureka district.—Leasing operations at the Pope-Shenon (Grandview) mine near Salmon in 1944 produced 199 tons of copper ore, which was shipped direct to a smelter.

Junction district.—The total output of the Junction district in 1944 was 40 tons of crude lead-silver ore shipped from the Bullion Apex and Plymouth properties near Leadore.

Texas district.—Milo W. Zook continued in 1944 to operate the Latest Out mine near Gilmore and shipped 725 tons of oxide lead-silver ore to a smelter in Utah.

Unorganized (Reno) district.—The Cabin mine near Reno was worked continuously in 1944, and 185 tons of oxide lead-silver ore were shipped to a smelter.

OWYHEE COUNTY

South Mountain district.—Mining of ore, containing sphalerite, galena, and chalcopryrite, at the Golconda mine by the South Mountain Mining Co. was continuous throughout the year. The company reported that 6,721 tons of zinc-lead-copper-silver ore were shipped to the International flotation mill at Tooele, Utah, where it was separated into lead-copper-silver concentrates, zinc concentrates, and iron concentrates.

SHOSHONE COUNTY

COEUR D'ALENE REGION

In 1944 the Coeur d'Alene region of Shoshone County remained the largest silver-producing area in the United States and ranked second in lead and zinc; it produced 87 percent of Idaho's silver, 76 percent of the copper, 92 percent of the lead, and 93 percent of the zinc. The value of the metal output of the region was \$38,307,297 compared with \$38,594,728 in 1943. The output of each metal except zinc decreased; gold declined 8 percent, silver 16 percent, copper 35 percent, and lead more than 14 percent. The output of zinc in 1944 exceeded the record of 1943 by 7 percent. The chief producers of zinc in the region in 1944, according to rank (each producing more than 12,000,000 pounds), were the Star, Bunker Hill & Sullivan zinc slag-fuming plant, Bunker Hill & Sullivan mine, Morning, Page, Osburn tailing plant, and Tamarack properties; the chief producers of lead, according to rank (each producing more than 7,000,000 pounds), were the Bunker Hill & Sullivan, Morning, Star, Page, Osburn tailing plant, Tamarack, and Sherman properties; and the chief producers of silver, according to rank (each producing more than 300,000 ounces), were the Sunshine, Polaris, Bunker Hill & Sullivan, Osburn tailing plant, Page, Silver Dollar, Morning, and Silver Syndicate properties.

Of the total material (2,765,483 tons) produced in 1944 in the Coeur d'Alene region, 84 percent was zinc-lead ore and old tailings, more than 8 percent lead-silver ore, 4 percent zinc slag, and nearly all the remainder silver ore.

Mine production of gold, silver, copper, lead, and zinc in the Coeur d'Alene region, Shoshone County, 1943-44, and total, 1884-1944, in terms of recovered metals

Year	Mines producing		Ore	Gold (lode and placer)	Silver (lode and placer)	Copper	Lead	Zinc	Total value
	Lode	Placer							
			Short tons	Fine ounces	Fine ounces	Pounds	Pounds	Pounds	
1943.....	47	3	2,270,385	2,250	10,302,840	3,974,000	179,626,000	159,268,000	\$38,594,728
1944.....	47	1	2,765,483	2,075	8,669,371	2,578,000	153,625,000	170,454,000	38,307,297
Total, 1884-1944.....			(1)	389,410	419,516,106	² 63,536	² 5,412,089	² 1,051,407	1,054,993,601

¹ Figures not available.

² Short tons.

Beaver district.—The output of the Beaver district in 1944 was 191,180 tons of zinc-lead ore and 6,600 tons of zinc ore compared with 55,922 tons of zinc-lead ore and 60 tons of lead ore in 1943. The most important output was 77,003 tons of ore, averaging 1.05 ounces of silver to the ton, 2.48 percent lead, and 5.82 percent zinc, from the Amazon-Carlisle-Portland groups (Monitor Mining Co.) treated in the Hercules, Dayrock, and Carlisle flotation mills near Wallace. According to the printed annual report of the Monitor Mining Co., the output of ore in 1944 was more than double that in 1943; however, labor shortages prevented full production. Since the fall of 1942 the company has completely equipped its four largest known ore bodies, the grade of which is low; present operations would not be profitable without premiums above the present ceiling prices of 6.50 cents a pound for lead and 8.25 cents for zinc. Despite the shortage of manpower, the Amazon and Carlisle ore bodies (and the Silver Tip to some extent) have been developed to a point where substantial reserves of low-grade ore are known to exist.

Sunset Lease worked the Sunset mine continuously and hauled 22,547 tons of zinc-lead ore to the Golconda custom flotation mill near Wallace. The rest of the district output comprised 6,600 tons of zinc ore from the Interstate-Callahan waste dump and 1,630 tons of zinc-lead ore from the Nipsic claim of the Interstate-Callahan group treated in the custom flotation mill of Zanetti Bros. near Wallace. An important body of zinc-lead ore was discovered in November in the Nipsic claim by Daylight Lease.

Eagle district.—The Crystal Lead Mines Co. operated its property near Murray in 1944 and hauled 994 tons of lead ore to the Hercules custom mill.

Evolution district.—The output of the Evolution district in 1944 comprised 724,121 tons of zinc-lead old tailings, 64,515 tons of lead-silver ore, 40,674 tons of silver ore, and 28,635 tons of silver-copper-antimony ore, compared with 127,318 tons of zinc-lead old tailings, 220,708 tons of silver-copper-antimony ore, 28,000 tons of silver ore, and 21,405 tons of lead-silver ore in 1943. Nearly all the old tailings in 1944 came from the Osburn dump, all the lead-silver ore and most of the silver ore from the Chester vein and the Silver Syndicate fault zone, and nearly all the silver-copper-antimony ore from the Mineral Point mine. The Osburn tailing dump became a large producer of silver, lead, and zinc in 1944 as a result of continuous operation of its 2,500-ton sink-and-float plant and 500-ton flotation mill by the Hecla Mining Co. The company reported that 720,521 tons of old tailings, containing an average of 1.25 ounces of silver to the ton, 1.60 percent lead, 1.75 percent zinc, and a little copper, were treated during the year in the sink-and-float plant; the resulting zinc-lead middling (500,317 tons) was treated in the Osburn, Polaris, and Hecla flotation mills where it was separated into lead concentrates and zinc concentrates. The output of silver-copper-antimony ore from the Sunshine mine of the Sunshine Mining Co. dropped from 141,955 tons in 1943 to 3,298 tons in 1944 as mining operations on the Sunshine vein were suspended in March to concentrate all available labor on mining lead-silver ore from the Chester vein and the Silver Syndicate fault zone. This mineral area (known as Rambo, Omega, and Rotbart) includes property owned by the Sunshine Mining Co., Polaris Mining Co., Silver Dollar Mining Co., and Silver Syndicate, Inc., but all explora-

tion, development, and mining and milling of ore are done by the Sunshine Mining Co. According to the printed annual report of the Sunshine Mining Co. for 1944, a conflict of ownership of ore in the Chester vein in territory adjacent to Sunshine's original east boundary was satisfactorily settled by an agreement creating the Rotbart area in which the ownership was divided equally between the Sunshine Mining Co., Polaris Mining Co., and Silver Dollar Mining Co. The Rotbart area has an east-west dimension of 400 feet and is contained within the Omega area, which continues for about 1,400 feet to the east of the Rotbart area. The Chester vein in the Omega area is owned in equal shares by the Sunshine Mining Co. and Polaris Mining Co. A new agreement was negotiated in 1944 with Silver Syndicate, Inc., in which Silver Syndicate conveyed to Sunshine a 50-percent interest in all Silver Syndicate mineral holdings, including apex rights on some 4,100 feet of length on the strike of the Silver Syndicate fault. The Chester vein has been developed in the Rotbart area on several levels with excellent results. The ore body appears to be wider and above average grade in this area; it is continuous from the 2,500 to the 3,100 level and may reasonably be expected to extend below the 3,700 level. Much additional work will be required to determine fully the extent of the ore zone on the 3,700 level. The most extensive development to date has been on the 3,100 level where the ore is continuous for a length of 1,000 feet. Development in all areas in 1944 comprised 3,985 feet of drifting, 1,001 feet of raising, and 1,208 feet of crosscutting; and diamond drilling of 21 test holes totaled 3,369 feet. Ore reserves were increased as a result of this development, and they will probably be further increased in 1945, resulting from work on the 3,700 level.

The company reported that the total output of ore from the Chester vein and Silver Syndicate fault zone was 91,956 tons (43,975 tons for Sunshine account and 47,981 tons for account of Polaris, Silver Dollar, and Silver Syndicate Co.), averaging 44.6 ounces of silver to the ton, 6.3 percent lead, and a little copper; the concentrates contained 4,052,478 ounces of silver, 881,944 pounds of copper, and 11,358,942 pounds of lead, of which the net for Sunshine account, including 84,685 ounces of silver, 31,485 pounds of copper, and 15,553 pounds of lead produced from the Sunshine vein, was 1,968,166 ounces of silver, 437,968 pounds of copper, and 5,599,246 pounds of lead. The production credited to other companies (Polaris, Silver Dollar, and Silver Syndicate) was 2,168,997 ounces of silver, 475,461 pounds of copper, and 5,775,249 pounds of lead. About 36,950 tons of lead-silver ore were mined in 1944 from the Chester vein by the Sunshine Mining Co. for Polaris Mining Co. account. In addition, 13,231 tons of silver ore from the Polaris vein were hauled to the Sunshine mill for treatment. The Polaris Mining Co. reported that silver ore previously developed in the Polaris vein was completely mined out in 1944 and that exploratory work failed to develop any additional ore. The Polaris 300-ton flotation mill near Osburn operated continuously throughout the year on zinc-lead middling produced at the Osburn sink-and-float plant.

Mining and milling of silver-copper-antimony ore at the Mineral Point property of the Coeur d'Alene Mines Corporation near Osburn were continuous throughout the year. The company reported that the 600-ton flotation mill treated 25,337 tons of ore in 1944 compared with

73,753 tons in 1943. During the first quarter of the year the silver-copper-antimony concentrates (454 tons) were shipped to the leaching and electrolytic antimony plant of the Sunshine Mining Co. to recover the antimony; however, this plant was closed in March and during the remainder of the year the concentrates were shipped direct to the smelter at Tacoma, Wash. According to the corporation printed annual report, the ore treated in 1944 averaged 12.55 ounces of silver to the ton, 1.02 percent copper, and 0.61 percent antimony. The concentrates (848 tons) contained 313,414 ounces of silver, 510,189 pounds of copper, and 303,009 pounds of antimony—a marked decrease from the metal output in 1943. Production was curtailed throughout the year, owing to the difficulty of obtaining miners. Development in 1944, principally on the 2,200 level, comprised 1,068 feet of drifting, 976 feet of crosscutting, and 2,194 feet of diamond drilling. The ore reserves at the end of the year were estimated at 72,369 tons, which is considerably lower than the estimate of December 31, 1943, due to the fact that much ore included in the estimate at that time has proved too low-grade to have commercial value.

Hunter district (Mullan).—A total of 528,015 tons of ore was produced in 1944 from 6 properties in the Hunter district, compared with 539,705 tons of ore from 8 properties in 1943; the most important output was 472,331 tons of zinc-lead ore from the Morning and Star mines. Mining and milling operations at the Morning property of the Federal Mining & Smelting Co. at Mullan continued throughout the year. The 1,250-ton mill treated 163,931 tons of waste-dump ore containing an average of 0.7 ounce of silver to the ton, 1.2 percent lead, and 1.0 percent zinc, and 112,838 tons of mine ore containing an average of 2.2 ounces of silver to the ton, 6.2 percent lead, and 7.3 percent zinc. According to the printed annual report of the company for 1944, operations were on a basis of 6 days per week throughout the year; the mine operated 2 shifts a day until April 24 and 1 shift thereafter owing to a labor shortage. A severe rock burst on May 9 caused considerable damage to the stopes on the 4,250 and 4,450 levels, resulting in a loss in tonnage and grade of ore mined during May and June. The labor shortage continued, with a net loss of 175 men during the year. The crew on January 1, 1945, was about 240 men below normal, and no new labor is available. The shortage of labor was so pronounced in 1944 that the company was unable to conduct the development and shaft sinking which normally would have been done. Obviously, there is a limit to postponement of this work. The war emergency, however, justifies the action so far taken. Ore reserves at the end of the year, including developed and probable ore in both the Morning and You-Like portions of the mine, are estimated at 530,000 tons, a decrease of 90,000 tons from the estimated tonnage at the end of 1943; possible ore is not considered.

The Star mine and 1,000-ton flotation mill of the Sullivan Mining Co. at Burke were operated continuously in 1944 but at a lower rate than in 1943 owing to a shortage of miners; the mill treated 195,562 tons of zinc-lead ore (238,509 tons in 1943), yielding 9,743 tons of lead concentrates and 30,740 tons of zinc concentrates, which contained 145 ounces of gold, 229,819 ounces of silver, 15,620,767 pounds of lead, and 32,078,369 pounds of zinc. The mine continued as the largest producer of zinc in Idaho. Hunter Lease operated the Gold Hunter mine and 500-ton flotation mill at Mullan throughout the

year; 46,200 tons of ore averaging 3.03 ounces of silver to the ton, 2.64 percent lead, and 0.72 percent zinc were treated in 1944 compared with 52,760 tons in 1943. No zinc concentrates were produced in 1944, but the company reported that work was begun late in the year in equipping the mill with a zinc flotation unit. The remainder of the district output comprised 4,581 tons of zinc-lead-silver ore from the Lucky Friday mine treated in the Golconda custom mill, 4,318 tons of lead ore from the Atlas mine treated in Zanetti Bros. custom mill, and 585 tons of zinc-lead ore from the Golconda mine.

Lelande district (Burke, Mace, Frisco).—The output of the Lelande district was 136,180 tons of zinc-lead-silver ore and old tailings and 31,748 tons of lead ore in 1944 compared with 256,732 tons of zinc-lead-silver ore and old tailings, 56,217 tons of lead ore, and 50 tons of mill cleanings in 1943. The output of zinc-lead-silver ore from the Hecla mine at Burke decreased from 140,400 tons in 1943 to 26,040 tons in 1944 as production from the mine ceased in July owing to exhaustion of ore reserves. The property has been one of the principal producers of silver and lead in the State since 1902 and a large producer of zinc since 1929. According to the printed annual report of the Hecla Mining Co. for 1944, all ore remaining in the mine was worked out during the year; however, the surface facilities at Burke and the Hecla shaft will be used to service the Star mine of the Sullivan Mining Co., 50 percent of which is owned by the Hecla Mining Co. The Hecla 900-ton flotation mill was operated continuously, mainly on zinc-lead middling produced at the Osburn sink-and-float tailing plant.

A total of 54,851 tons of zinc-lead-silver ore was produced in 1944 from the Frisco mine near Gem owned by the Federal Mining & Smelting Co.; the company worked the lower levels of the mine throughout the year and hauled 30,519 tons of ore (containing an average of 1.35 ounces of silver to the ton, 3.89 percent lead, and 5.75 percent zinc) to the Morning flotation mill at Mullan, and Hull Lease worked the upper levels and treated 24,332 tons of similar ore in its own 90-ton flotation mill at Gem. According to the printed annual report of the Federal Mining & Smelting Co., the decrease in output of ore from the Frisco mine in 1944 resulted from a shortage of labor; during the year the crew lost 30 men. Ore reserves at the end of the year were estimated at 215,000 tons of developed and probable ore. From present indications, additional ore will be developed as the lower levels are made accessible.

Mining and milling at the Sherman property were continuous by the Sherman Lead Co.; however, the drop in output of lead ore from 56,217 tons in 1943 to 31,731 tons in 1944 resulted entirely from paucity of labor. The ore, milled in the company 300-ton flotation plant, contained 268,323 ounces of silver, 7,880,200 pounds of lead, and 1,492,600 pounds of zinc. According to the printed annual report of the company, no zinc concentrates were produced in 1944, as a greater economic return for zinc was secured through premium payments allowed by the quota committee of the War Production Board for zinc contained in the lead concentrates than could have been obtained in a separate mill zinc concentrate. The Sherman mine and mill are in excellent condition, and output of ore can be increased whenever additional manpower is available; full-scale operation of the mine requires not less than 125 men. Despite all efforts made by the company in cooperation with the War Manpower Commission

and the United States Employment Service, it was difficult to maintain the crew at 50.

Virtually all the remainder of the district output was old tailings (5,289 tons) deposited along Canyon Creek above Wallace and owned by the Small Leasing Co. The company reported that 36,671 tons of material, containing an average of 2.5 ounces of silver to the ton, 3.0 percent lead, and 4.5 percent zinc, were treated in the Fordosa flotation mill on the property, and 18,618 tons of similar material were hauled to the Golconda custom flotation mill for treatment.

Placer Center district.—Of the total material (185,581 tons) produced in 1944 in the Placer Center district, 124,688 tons were zinc-lead-silver ore, 32,911 tons lead-silver ore, and 27,982 tons zinc-lead old tailings. The most important output was 94,527 tons of zinc-lead-silver ore produced from the Tamarack mine by the Tamarack & Custer Consolidated Mining Co. The ore, containing 134,060 ounces of silver, 9,322,120 pounds of lead, and 13,983,740 pounds of zinc, was treated in the company 400-ton flotation mill and yielded 5,269 tons of lead-silver concentrates and 11,618 tons of zinc concentrates. According to the printed annual report of the company, the Tamarack mine and mill were operated continuously in 1944 but at a lower rate than in 1943 owing to a shortage of labor. An average crew of at least 200 men is required to maintain normal production and development. At the beginning of 1944 the company employed 169 workers, but at the end of the year the number had fallen to 115. The mine and mill are in good condition and ready for maximum production whenever manpower is available. Development was about the same in 1944 as in 1943, but not as much new ore was discovered as was extracted; hence, the ore reserves declined moderately.

The Dayrock Mining Co. operated its mine and 220-ton flotation mill continuously in 1944; a total of 32,833 tons of ore averaging 3.72 ounces of silver to the ton, 4.92 percent lead, and 0.60 percent zinc was treated in the Dayrock and Hercules milling plants and yielded 2,302 tons of high-grade silver-lead concentrates. According to the company printed annual report, the average crew at the mine in 1944 was 47 men, or about 60 percent of the working force necessary to maintain capacity production and normal development. During the year the ore reserves were increased materially by the development of rather low-grade ore (estimated at 3.3 ounces of silver to the ton and 5.4 percent lead) in the Ohio vein. It is doubtful if this new tonnage can be profitably extracted at a lead price of 6.5 cents a pound.

About 21,440 tons of zinc-lead ore were produced in 1944 from the Red Monarch, Rex, and Delaware groups near Wallace by the Callahan Consolidated Mines Co.; the ore, averaging 0.85 ounce of silver to the ton, 2.83 percent lead, and 4.54 percent zinc, was treated in the company 100-ton flotation mill. The remainder of the district output was principally 27,982 tons of zinc-lead old tailings from the Mary Jones, Tomsche, Vermillion, and Zanetti properties, 6,000 tons of zinc-lead ore from the Black Jack waste dump, and 2,141 tons of zinc-lead ore from the Success mine—all treated in custom flotation mills near Wallace.

Yreka district (Kellogg).—The output of the Yreka district in 1944 comprised 739,326 tons of zinc-lead-silver ore and old tailings, 115,281 tons of zinc slag, 47,783 tons of silver-lead-iron old tailings, and

14,850 tons of silver-lead ore—a total of 917,240 tons, the largest output in any district of Idaho and an increase of 19 percent over 1943. The most important output was 251,062 tons of zinc-lead-silver ore from the Bunker Hill & Sullivan mine at Kellogg, although its output was 30 percent less than in 1943. In addition, 7,179 tons of silver-lead ore were produced by lessees from the upper levels of the mine, and the company treated 47,783 tons of silver-lead-iron old jig tailings in a 300-ton gravity-flotation plant which yielded 5,138 tons of low-grade silver-lead-iron concentrates and 6,979 tons of high-grade iron concentrates. The company main 1,700-ton flotation mill, equipped with a sink-and-float unit, operated continuously and treated 251,062 tons of zinc-silver ore from the Bunker Hill & Sullivan mine and 215,373 tons of zinc-lead old tailings from the Sweeny dump; E. G. Smith operated a portion of the Sweeny tailing dump during the first 6 months of the year and treated about 10,000 tons of similar material in the Crescent flotation mill, which he leased. The Bunker Hill & Sullivan mine remained the largest producer of lead in Idaho and ranked third in silver and zinc. According to the company printed annual report, there were produced and recovered from Bunker Hill & Sullivan mine ore (including lessee ore) 922,716 ounces of silver, 29,655,000 pounds of lead, and 18,502,000 pounds of zinc. Because of a pronounced shortage in manpower, especially for underground mine labor, metals recovered in 1944 decreased sharply compared with 1943. There was not only a decrease in mine production but also in amount of mine development and prospecting accomplished during the year, which resulted in a slightly smaller tonnage of ore in reserve as compared with 1943, although the net tonnage remains very satisfactory. Ore reserves January 1, 1945, undercut and available for mining, totaled 2,778,539 tons of zinc-lead-silver ore. Operations at the zinc slag-fuming plant of the Bunker Hill & Sullivan Mining & Concentrating Co. at Bradley were carried on throughout the year at a much greater rate than in 1943, resulting in a 79-percent increase in production of zinc. In 1944 the plant treated 78,106 tons of old reclaimed dump slag and 76,664 tons of hot current slag from the lead furnaces of the Bunker Hill smelter at Bradley, but only the old dump slag and 37,175 tons of the hot slag were credited directly to the fuming-plant operation as a primary producer; the remainder of the hot slag was originally lead concentrates (containing zinc) shipped by various companies, chiefly in the Coeur d'Alene region, to the lead furnaces of the Bunker Hill smelter.

Mining and milling of zinc-lead-silver ore from the Blackhawk and Page mines by the Federal Mining & Smelting Co. were continuous in 1944 but at a lower rate than in 1943 owing to a shortage of miners. The company reported that 116,976 tons of ore from the Page mine and 2,223 tons of ore from the Blackhawk mine, containing an average of 4.26 ounces of silver to the ton, 7.14 percent lead, and 7.74 percent zinc, were treated in the Page 500-ton flotation mill. According to the printed annual report of the company, no shaft sinking was done during the year. On the 2,400 level of the Page mine the drift eastward on the Tony vein was driven 651 feet in 1944—the ore shoot on this level is 2,300 feet long. On the 2,100 level the drift eastward on the same vein was driven 625 feet, and the ore shoot is 1,945 feet long. The ore developed on both levels is of good average width and excellent grade. The new development has substantially increased the

reserves. Ore reserves at the end of the year were estimated at 35,000 tons of developed and probable ore—an increase of 100,000 tons over the estimated tonnage at the end of 1943.

The Highland-Surprise Consolidated Mining Co. operated its mine and mill continuously; the 150-ton flotation mill treated 34,857 tons of zinc-lead ore (18,130 tons in 1943), yielding 5,436 tons of zinc-lead concentrates. In 1944 the capacity of the 100-ton flotation mill at the Little Pittsburg property was increased to 125 tons of ore a day by the Denver Development Co.; during the year the mill treated 354 tons of zinc-lead ore yielding 5,754 tons of zinc-lead concentrates. Mining and milling were continued throughout the year at the Douglas mine on Pine Creek by the Small Leasing Co.; the company 100-ton flotation mill treated 23,608 tons of zinc-lead ore yielding 3,538 tons of zinc-lead concentrates. Late in the year the Spokane-Idaho Mining Co. changed its milling practice from producing a bulk zinc-lead concentrate to producing two products—a high-grade lead concentrate and a zinc-lead concentrate. During the year the company 150-ton flotation mill treated 22,246 tons of zinc-lead ore yielding 3,807 tons of zinc-lead concentrates and 182 tons of high-grade lead concentrates. The Nabob mine on Denver Creek was taken over in January 1944 under lease by the Lynch-Pine Creek Mining Co.; during the year this company hauled 16,248 tons of zinc-lead ore to the Amy Matchless flotation mill on Pine Creek, where the ore was beneficiated to 534 tons of lead concentrates and 1,491 tons of zinc concentrates. The Sidney mine, also on Denver Creek, was operated continuously in 1944 by the Sidney Mining Co. The company reported that 12,215 tons of zinc-lead ore were treated in its 50-ton flotation mill and that diamond drilling by the Bureau of Mines and underground development by the Sidney Mining Co. opened an extensive body of zinc-lead ore. The rest of the district output was principally 7,671 tons of silver-lead ore produced from the Liberal King mine by Sunset Mineral, Inc., and treated by flotation.

VALLEY COUNTY

Deadwood Basin district.—The Callahan Zinc-Lead Co. operated the Hall-Interstate property and its 100-ton flotation mill at Deadwood continuously in 1944. According to the company printed annual report, only 5,263 tons of zinc-lead-silver ore were milled during the first 8 months of the year, as the time was devoted primarily to development. Productive operations were resumed in September, and during the rest of the year the mill treated 10,525 tons of zinc-lead-silver ore.

Yellow Pine district.—The capacity of the Yellow Pine mill at Subnite was increased to 800 tons of ore a day in 1944, and during the year 211,382 tons of gold-silver-iron-antimony-tungsten ore, taken from an open pit at the mine, were treated by flotation. The mill yielded 3,573 tons of high-grade tungsten concentrates, 8,807 tons of low-grade tungsten concentrates, 6,975 tons of antimony-silver-gold concentrates, and 4,103 tons of gold-silver-antimony-iron concentrates. The property was the largest producer of gold, antimony, and tungsten in Idaho in 1944.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN MONTANA

(MINE REPORT)

By G. E. WOODWARD AND PAUL LUFF

SUMMARY

Copper ore remained the chief source of metal value in Montana in 1944; the value of the metals recovered from copper ore and its products was \$35,998,281 or 73 percent of the State total. The total value of the gold, silver, copper, lead, and zinc produced from Montana ores and gravels was, in terms of recovered metals, \$49,039,855, compared with \$53,642,658 in 1943. (See fig. 1.) This 9-percent decrease resulted from a smaller output of each metal; however, the value of the zinc output was greater owing to the higher average price of the metal. The total value (\$1,750,735) of the gold output declined 16 percent; silver (\$5,044,064), 16 percent; copper (\$31,911,300), 9 percent; and lead (\$2,096,800), 14 percent. The value (\$8,236,956) of the zinc output increased 1 percent. Silver Bow County, which yielded virtually all the copper output of the State and most of the silver, produced gold, silver, copper, lead, and zinc valued at \$38,877,303, compared with \$42,100,656 in 1943. The decrease resulted from a smaller output of gold, silver, and copper, as the yield of lead and zinc was greater.

Production of gold, silver, copper, lead, and zinc in Montana in 1944 was affected by several factors: An acute shortage of labor which was the primary cause of a loss in output of gold, silver, and copper; the marked decrease in output of direct-smelting copper ore from mines at Butte; the suspension in May of mining siliceous silver ore at the Flathead mine near Kila; the permanent shut-down in April of the Perry-Schroeder bucket dredge near Helena; the closing in September of the Boaz gold mine at Norris; the beginning in February of milling gold-arsenic ore at the Jardine property at Jardine; and the decrease in treatment of zinc slag and zinc-lead ore.

Considerable assistance was given to mine operators in Montana in 1944 by the Grazing and Forest Services through the building of access roads to various properties. Most of the roads approved for construction were to zinc-lead properties in Cascade, Gallatin, Lincoln, Powell, and Sanders Counties; roads were constructed also to a copper deposit in Beaverhead County, a lead deposit in Meagher County, an antimony deposit in Sanders County, mica deposits in Madison County, corundum deposits in Gallatin County, a barite deposit in Missoula County, and coal mines in Chouteau, Madison, and Rosebud Counties. The Bureau of Mines, in cooperation with the Geological

Survey, did considerable work in 1944, exploring and testing various properties throughout the State. Most of this work was drilling test holes at the Running Wolf iron deposits in Judith Basin County, Sheep Creek iron deposit in Meagher County, Southern Cross iron deposit in Deer Lodge County, corundum deposits in Gallatin and Madison Counties, optical calcite deposits in Sweet Grass County, Johnny Gulch talc deposit in Madison County, zinc-lead mines in Cascade and Madison Counties, and copper deposits in Granite, Madison, and Silver Bow Counties.

The ceiling prices of copper, lead, and zinc have not changed since February 1942; copper has been 12 cents a pound, lead 6½ cents (New York), and zinc 8½ cents. To augment the prices for these metals the Government policy of premium payments for overquota production of copper, lead, and zinc remained in force throughout 1944.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063
1941.....	35.00	0.711+	.118	.057	.075
1942.....	35.00	0.711+	.121	.067	.093
1943.....	35.00	0.711+	.130	.075	.108
1944.....	35.00	0.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1937, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price of bonus payments by Metals Reserve Company for overquota production.

⁴ Minimum.

Mine production of gold, silver, copper, lead, and zinc in Montana, 1940-44, and total, 1882-1944, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1940.....	687	285	5,099,241	272,602	\$9,541,070	12,361,050	\$8,790,090

¹ Floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Montana, 1870-1944.

Gold.—Montana ores and gravels yielded 50,021 fine ounces of gold in 1944, compared with 59,586 ounces in 1943—a 16-percent decrease; the output from lode mines decreased 1,716 ounces and from placer mines 7,849 ounces. Marked decreases in gold output at the Boaz mine and the Perry-Schroeder bucket dredge more than offset a substantial increase at the Jardine mine. War Production Limitation

Order L-208 restricting production from gold mines remained in effect throughout 1944; however, grants for continuation of operation were extended to four producers in Montana in 1944. These mines justified their operation by reason of supplying a special product to the Government or smelters or because exhaustion of the mineral deposits was near completion. Siliceous ores (chiefly gold ore) yielded 51 percent of the State total gold, base-metal ores (mainly copper ore and zinc-lead ore) 36 percent, and placers 13 percent. Gold recovered from gold ore and base-metal ores was virtually the same as in 1943, but gold from siliceous silver ore declined 1,426 ounces. More than 85 percent of the State total gold came from properties in the Summit Valley (Butte), Sheepeater (Jardine), Whitehall, New World (Cooke City), Henderson, Flint Creek (Philipsburg), Missouri River, Marysville, and Norris districts. Gold ore mined totaled 97,928 tons, compared with 72,616 tons in 1943, and comprised 50,935 tons treated in amalgamation and cyanidation mills, 21,352 tons in concentrating mills, and 25,641 tons shipped crude to smelters. Ore treated at amalgamation and cyanidation mills (with or without concentrating equipment) yielded more than 14 percent of the State total gold; ore concentrated, 40 percent; and ore of all classes shipped crude to smelters, 33 percent. Two floating connected-bucket dredges were active in 1944; however, one of these—Perry-Schroeder 6-cubic foot (90-bucket) dredge on the Missouri River in Lewis and Clark County—ceased operations April 12, 1944, owing to exhaustion of profitable gravel. The other (H. & H. Mines 3½-cubic foot bucket dredge on Henderson Creek in Granite County) remained in operation through December and is still operating in 1945, because this dredge recovers tungsten in addition to gold.

The leading gold producers in Montana in 1944 were: All the company-operated copper mines, waste dumps, tailing dumps, and slime ponds of the Anaconda Copper Mining Co. at Butte and Anaconda; the Jardine mine at Jardine; the Golden Sunlight mine near Whitehall; the Estelle mine at Cooke City; the H. & H. dredge near Hall; the Granite-Bimetallic tailing dump at Philipsburg; the Perry-Schroeder dredge near Helena; and the Boaz mine at Norris.

Silver.—The output of recoverable silver in Montana was 7,093,215 fine ounces in 1944 compared with 8,450,370 ounces in 1943—a 16-percent decrease. The principal decreases were in the Summit Valley (Butte), Hog Heaven, Barker, Montana, Elkhorn, Colorado, and Heddlleston districts. Ore treated at concentrating mills yielded 88 percent of the total silver and smelting ore 11 percent; the remainder came largely from slag fumed. Copper ore yielded 78 percent of the State total silver; zinc-lead ore 11 percent; siliceous ores 9 percent; and lead ore and zinc ore 2 percent. The output of silver from siliceous silver ore declined 692,950 ounces, that from copper ore 497,540 ounces, that from zinc-lead ore 195,983 ounces, and that from lead ore 15,598 ounces, but silver from zinc ore and slag increased 34,537 ounces.

Copper mines, mine dumps, tailing dumps, slime ponds, and zinc mines and the North Butte property (all at either Butte or Anaconda) and the Flathead mine (in Flathead County)—all operated by the Anaconda Copper Mining Co.—produced 79 percent of the State total silver in 1944. Other large producers included the Emma mine at Butte (all byproduct silver), the Granite-Bimetallic tailing dump at Philipsburg, and the Mike Horse mine near Flesher in Lewis and Clark County.

Copper.—Copper produced in Montana, in terms of recovered metal, was 236,380,000 pounds in 1944 compared with 269,050,000 pounds in 1943—a 12-percent decrease. The Anaconda Copper Mining Co. was the only important copper producer in Montana and contributed 99 percent of the State copper output. The company treated a greater tonnage of copper material than in 1943; the lower copper content resulted from the treatment of more old tailings and slime ponds. All the copper mines at Butte are owned or operated by the Anaconda Copper Mining Co. Copper produced from mine ore at Butte decreased, but that derived from the treatment of mine dumps at Butte and old tailing dumps and slime ponds at Anaconda increased. Virtually all the waste materials at Anaconda were derived from the earlier treatment of ore from copper mines at Butte.

Lead and zinc.—The output of recoverable lead in Montana in 1944 was 26,210,000 pounds—a 20-percent decrease from 1943, and the output of recoverable zinc was 72,254,000 pounds—a 4-percent decrease. The slag-fuming plant at East Helena, operated by the Anaconda Copper Mining Co., showed a decrease of about 2,175,000 pounds in lead and 8,170,000 pounds in zinc. The Emma mine at Butte, operated by the Anaconda Copper Mining Co. under lease, showed a decrease of about 1,225,000 pounds in byproduct lead and about 531,000 pounds in zinc; no zinc-lead ore was mined from this property in 1944. About 70 percent of the State lead output was recovered from zinc-lead ore, 11 percent from zinc ore and slag, 10 percent from lead ore, and 9 percent from siliceous ores.

The leading sources of zinc in 1944, named in order of output, were the slag-fuming plant at East Helena (about 56 percent of the State total), the Emma byproduct zinc, the Poulin mine at Butte, the Mike Horse mine near Flesher, the Silver Cable mine near Saltese, the Toledo-Buckeye group near Sheridan, and the Mount Washington mine at Wickes. About 59 percent of the State zinc output was recovered from zinc ore and slag and nearly all the remainder from zinc-lead ore.

The leading producers of lead in 1944 were the Mike Horse, the Emma byproduct lead, the slag-fuming plant at East Helena, the Jack Waite, Poulin, and Mount Washington properties, and the Hecla slag dump; these seven sources contributed more than 62 percent of the State total.

MINING INDUSTRY

In spite of a serious labor shortage throughout the various mining districts in Montana in 1944, the total ore, old tailings, and slag mined or treated was greater than in 1943; however, the output of each metal (gold, silver, copper, lead, and zinc) was less. Copper ore mined at Butte declined from 3,377,318 to 2,559,796 tons, but waste-dump ore increased from 492,673 to 879,879 tons and old tailings and slimes mined at Anaconda increased from 1,243,133 to 1,906,626 tons. The State output of zinc-lead ore (mined principally in the Butte, Heddleston, Sheridan, Montana (Neihart), Dunkleberg, and Colorado (Wickes) districts) declined from 294,369 to 258,874 tons, zinc ore and slag from 234,361 to 201,470 tons, and silver ore from 140,466 to 65,317 tons; gold ore (mined principally in the Sheep-eater, New World, and Whitehall districts) increased from 72,616 to 97,928 tons, gold-silver ore (largely old tailings mined from a property in the Flint Creek district) from 53,890 to 68,154 tons, and lead ore from 8,449 to 16,857 tons.

Two connected-bucket floating dredges were active in Montana in 1944—one near Hall in Granite County and the other near Helena in Lewis and Clark County. They treated 1,197,600 cubic yards of gravel and recovered gold valued at \$206,045, indicating an average recoverable gold value of 17 cents per cubic yard treated. No dragline floating or dry-land dredges were active in Montana in 1944.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Montana in 1944, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

Total, 1943.....	272	5,873,016	59,586	8,450,370	*269,050,000	32,648,000	75,212,000

*Includes 4,713,664 pounds recovered from precipitates.

†Includes 187,988 tons of current slag fumed.

‡A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

§Includes 4,369,199 pounds recovered from precipitates.

METALLURGIC INDUSTRY

The 6,049,462 tons of ore produced from Montana lode mines in 1944 were treated as follows: 505 tons at amalgamation mills, 50,430 tons at amalgamation-cyanidation-concentration mills, 5,569,756 tons at concentrating mills, 240,783 tons shipped to smelters, and 187,988 tons of slag fumed.

One amalgamation-cyanide-concentration mill at Jardine, Park County, was active in Montana in 1944; it reported that 50,430 tons of gold-arsenic ore were treated, consuming 228 pounds of quicksilver, 34,000 pounds of calcium cyanide, 1,600 pounds of zinc dust, and 42,500 pounds of lime. The ore contained 10,641 ounces of gold and some silver and arsenic; the calcines and concentrates, containing principally gold, were shipped to smelters, gold bullion was sold to the United States Assay Office at Seattle, Wash., and arsenic trioxide was sold to the Government.

A total of 5,569,756 tons of ore of all classes was treated in straight concentration plants, compared with 5,327,448 tons in 1943. The 1944 total comprised 42,981 tons of siliceous ores, 5,272,359 tons of copper ore, 8,713 tons of lead ore, 2,666 tons of zinc ore, and 243,037 tons of zinc-lead ore.

The Anaconda Copper Mining Co. operated its electrolytic zinc plants at Anaconda and Great Falls without interruption in 1944. The Anaconda section had 5 units and the Great Falls section 10 units. The total rated capacity of the 15 units is 245,000 tons of slab zinc per year. In 1944 the average unit production of slab zinc per month was about 2,495,000 pounds, and, in addition, zinc dross was produced at a rate of about 46,000 pounds of contained zinc per unit per month, or a total of 2,541,000 pounds of zinc per month. The dross was sold to other plants for their use. Zinc concentrates were received and treated from most of the Western States, but chiefly from Idaho, Utah, Montana, Washington, Nevada, New Mexico, and California. In addition to domestic concentrates treated, the Anaconda and Great Falls plants treated about 210,000 tons of zinc concentrates from foreign sources, chiefly upon a toll basis, for accounts of the Metals Reserve Company. These concentrates originated from mines in Canada, Mexico, Peru, Chile, and Australia, as follows (quantities approximate): Canada, 50,000 tons; Mexico, 82,000 tons; Peru, 10,000 tons; Chile, 19,000 tons; and Australia, 49,000 tons. At Anaconda the copper smelter operated continuously. The company has 3 concentrating units at Anaconda—a copper concentrator with a daily rated capacity of 12,320 tons of ore, a zinc concentrator with a daily rated capacity of 2,000 tons, and a slime-disintegrating plant with a daily rated capacity of 2,000 tons. The copper concentrator is divided into 2 mills—the west mill and the east mill; the west mill has 3 identical sections, and the east mill has 4 sections; both mills treated only copper material in 1944. The zinc concentrator treated sulfide concentrates from manganese ores; the crushing, grinding, and some flotation equipment was used for treatment of copper mine dumps from Butte. The slime-disintegrating plant treats slime deposits. The American Smelting & Refining Co. operated its lead smelter at East Helena continuously in 1944, except for a brief period in May when the plant was shut down, principally for repairing and cleaning the flue systems.

Details of the treatment of all ores produced in Montana in 1944 are given in the tables that follow.

Mine production of metals in Montana in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

¹ Barker district lies in Cascade and Judith Basin Counties.

BEAVERHEAD COUNTY

Argenta district.—A total of 1,398 tons of ore was produced from mines in the Argenta district in 1944; 833 tons of lead ore and 31 tons of zinc-lead ore came from the Iron Mountain property, 524 tons of lead ore from the Louis Phillip mine, and 10 tons of gold ore from the El Fino mine. Most of the ore was shipped to smelters.

Bannack district.—In 1944 G. D. Hartman shipped 63 tons of gold ore from the Pioneer mine to the Anaconda copper smelter.

Bryant district.—L. D. Foreman continued to operate the Hecla mine and dumps in 1944 and shipped a total of 8,336 tons of siliceous gold ore, lead ore, zinc-lead ore, silver-lead tailings, and slag to smelters in Utah. The total output included 5,963 tons of old smelter slag containing an average of 6.4 percent lead and 7.8 percent zinc and minor quantities of gold, silver, and copper. The slag was smelted first in the Tooele lead blast furnace, and the resultant hot slag was treated in the slag-fuming furnace at Tooele for recovery of zinc-lead oxide fume.

Horse Prairie Creek or Colorado district.—A small lot of lead ore from the H & S mine was shipped in 1944 to the East Helena lead smelter, and placer gold was recovered by sluicing at the Gold Leaf property on Jeff Davis Creek.

Lipond district.—The Quartz Hill Leasing Co. operated Quartz Hill Mines in 1944 and shipped highly siliceous silver ore to the Anaconda copper smelter. Some of the ore contained enough silica for use as converter flux. Other production in the district was a small lot of silver ore from the Monte Cristo claim and a small lot of gold ore from the Star claim.

BROADWATER COUNTY

Beaver district.—The bulk of the output of the Beaver district in 1944 came from operations of the East Pacific and East Pacific Tunnel No. 4 claims. The property was worked continuously in 1944, and during the year a 30-ton gravity-concentration mill was built; 3,000 tons of silver-lead old tailings were treated, which yielded 289 tons of lead concentrates. In addition, 458 tons of crude silver-lead ore were shipped to a smelter and 105 tons of zinc-lead ore to the Midvale (Utah) custom concentrator. Other production in the district was 145 tons of gold ore shipped to a smelter from the Vosburg, Edna No. 2, Native Silver, and Joe Dandy mines and 88 tons of zinc-lead ore shipped from the January claim.

Cedar Plains district.—A total of 731 tons of lead ore and zinc-lead ore was produced from mines in the Cedar Plains district in 1944. It comprised 526 tons of zinc-lead ore from the North Star and Ruby Silver properties and 205 tons of lead ore from the Cleo, Dandy, and Santa Anita properties.

Park or Indian Creek district.—The Broadwater Zinc & Lead Co. operated its Iron Mask property throughout 1944 and shipped 4,885 tons of zinc ore to the East Helena lead smelter. Zinc was recovered by fuming the hot slag that resulted from smelting the ore first in the lead blast furnace at East Helena. In addition, the company treated approximately 1,000 tons of silver ore in its 50-ton concentration mill, which yielded 291 tons of zinc-lead concentrates. The remainder of the district production was gold ore and included 75 tons smelted from the Little Giant and Marietta properties and 412 tons amalgamated from the Diamond Hill and Silver Star properties.

CASCADE COUNTY

Barker district.—Andrew Fineide and Edward Thomson operated the Fairplay & Bon Ton group throughout 1944 and shipped 525 tons of zinc-lead ore to the custom concentrator at Midvale, Utah. The ore averaged about 5.3 ounces of silver to the ton, 25.7 percent zinc, 9 percent lead, and minor quantities of gold and copper.

Montana district.—The value of the metal output in the Montana district in 1944 was \$343,865 compared with \$278,396 in 1943; a substantial increase in production of zinc with smaller gains in production of lead and copper accounted for the increased value of the output. Virtually all the output was zinc-lead ore and silver ore treated in four flotation mills in the district. The Bennett Mining Co., assisted financially by the Reconstruction Finance Corporation, reopened the Dacotah group late in 1943 after the property had been idle over 30 years. In 1944 the company treated 12,286 tons of zinc-lead ore in the Florence 75-ton flotation mill, which yielded 339 tons of lead concentrates and 1,056 tons of zinc concentrates. The Neihart Mine & Milling Co. operated the Broadwater group and 80-ton flotation mill (formerly known as the Klies mill) throughout 1944. The company treated 19,002 tons of zinc-lead ore (containing 4.5 ounces of silver to the ton, 2.6 percent lead, and 2.4 percent zinc), which yielded 529 tons of lead concentrates and 446 tons of zinc concentrates. A total of about 11,400 tons of silver ore from the Star-Galt-London groups was treated in the 40-ton Star flotation mill by the New London Mining Co.; the resulting zinc-lead concentrates (198 tons) were shipped to the East Helena lead smelter. About 3,400 tons of gold-silver ore from the Benton group and 1,661 tons of silver ore from the Ripple mine were treated in the 100-ton Lexington flotation mill in 1944 by the Montana Leasing Co.; the resulting zinc-lead concentrates produced from the gold-silver ore and the silver-lead concentrates from the silver ore were shipped to a lead smelter. A little silver ore was produced also from the Minute Man mine.

FERGUS COUNTY

Cone Butte district.—A car of copper ore from the North group was shipped in 1944 to the Anaconda Copper Co. smelter by the Hamilton Copper Co.

FLATHEAD COUNTY

Hog Heaven district.—The output in the Hog Heaven district in 1944 was all siliceous silver ore shipped to a smelter. The Flathead and West Flathead mines, owned and operated by the Anaconda Copper Mining Co., produced 3,181 tons of ore, which was shipped to the Washoe Sampling Works at Anaconda; the remainder of the district production was 39 tons of silver ore shipped from the Flag-Martin mine.

GRANITE COUNTY

Boulder and South Boulder district.—Leon Heroux shipped a small lot of lead ore rich in silver from the Annie claim in 1944 to the East Helena smelter. The placer output was negligible.

Dunkleberg district.—All the output of the Dunkleberg district in 1944 came from the Forest Ross mine, operated under lease by the

Forest Rose Syndicate The company 80-ton flotation mill was operated throughout the year and treated 17,064 tons of zinc-lead ore, recovering 415 tons of lead concentrates and 690 tons of zinc concentrates. The ore treated contained an average of 2 percent lead and 3.4 percent zinc compared with an average content of 2.7 percent lead and 3.4 percent zinc in 1943. Considerable underground development was completed in 1944 in the Forest Rose mine.

First Chance district.—The Consolidated Mining Co., Inc., spent most of the year developing its Queen Helen mine of the Mitchell group; however, during the course of development 713 tons of silver ore were mined and shipped to the Washoe Sampling Works at Anaconda. The remainder of the district production was gold ore shipped to a smelter from the Homestake and Lynx properties and placer gold from the Lucky Jim and Ten Mile claims.

Flint Creek district.—In 1944, as in prior years, old tailings (silver) from the Granite-Bimetallic dumps were the chief source of metal production in the Flint Creek district. J. C. and Juanita Yob shipped 3,450 tons of these old tailings to the Tacoma (Wash.) smelter, to be used there as flux. Joseph T. Farrow operated the Two Per Cent property under lease until October 6, when all operations ceased. During the year 1,465 tons of zinc ore were shipped to the Anaconda zinc concentrator and 4 tons of crude silver ore to the Washoe Sampling Works. The Trout Mining Division of American Machine & Metals, Inc., produced chiefly manganese ore from its Trout mine in 1944; however, some sorted low-grade gold ore (1,942 tons) was shipped to smelters. Zinc ore (188 tons) was produced by the Moorlight Mining Co. from its Moorlight group, but the company's major output was high-grade manganese ore shipped mainly for use in the manufacture of batteries and lower-grade ore shipped to the Metals Reserve Company stock pile at Philipsburg. Zinc ore (84 tons) was produced also from the Silver Prince mine by the Contact Mines Corp., but its chief output was manganese ore. Other production in the district in 1944 was 44 tons of zinc ore from the Wenger No. 2 claim and 4 tons of copper ore from Comanche Extension claim.

Henderson district.—H. & H. Mines operated its floating connected-trucket dredge, equipped with $3\frac{1}{4}$ -cubic foot buckets, on Henderson Creek Gulch from March 21 to December 24 and recovered tungsten and abrasive sands in addition to gold and silver. During the period of operation, 50,000 cubic yards of overburden were moved and 620,000 cubic yards of gravel were washed, resulting in the recovery of 3,582 fine ounces of gold, 225 ounces of silver, 15,790 pounds of tungsten, and 88,000 pounds of abrasive sands. A special scheelite concentrator was operated in conjunction with the dredge.

JEFFERSON COUNTY

Boulder and Little Boulder district.—Silver ore (674 tons) from the Baltimore mine was shipped to the East Helena smelter.

Cataract district.—Many small operations were active in the Cataract district in 1944; the principal output was 1,063 tons of siliceous gold-silver tailings from the Blue Bird tailings dump shipped to the East Helena lead smelter for flux. O. O. Alexander and partners shipped 387 tons of zinc-lead ore to the Midvale (Utah) concentrator for treatment; J. K. Curtiss shipped 153 tons of gold-silver ore from

the Morning Glory mine to the Washoe Sampling Works at Anaconda; and Rufus Turner treated 70 tons of gold ore in his 25-ton amalgamation-concentration mill. The rest of the district output was mainly ore shipped crude to smelters from the Silver Hill, Klondyke, Bullion, Russell, Silver King, Comet, Crystal, Hope, and Boulder properties.

Colorado district.—The value of the metal output from the Colorado district decreased 4 percent compared with 1943; the output of gold and zinc increased, but that of silver, copper, and lead decreased. The Monongahela-Mount Washington Mining Co., by far the most important producer in the district, operated its Mount Washington mine throughout the year. The company 150-ton flotation mill ran during the first 2 months of 1944 and treated 6,318 tons of zinc-lead ore which yielded 136 tons of lead concentrates and 200 tons of zinc concentrates. Most of the zinc-lead ore mined was oxidized. In addition to the milling operation, the company made regular shipments of oxide zinc-lead ore to the East Helena smelter. The ore (6,607 tons) was smelted at the East Helena lead blast furnace, and the resulting slag was fumed for the recovery of zinc. Louis Peura and the American Smelting & Refining Co. worked the Minah waste dumps and shipped 3,720 tons of gold-silver ore to East Helena. The rest of the district output was principally silver ore and gold-silver ore from the Gregory mine and gold-silver ore from the Blizzard and Blue Bird properties.

Elkhorn district.—The Elkhorn dump continued in 1944 to be the chief source of metal production from the Elkhorn district; however, the output was about half that in 1943. A power shovel was used to load the old tailings, which were shipped to East Helena to be used there as flux; the material averaged 6.6 ounces of silver to the ton, 1.8 percent lead, and 4.5 percent zinc, with minor quantities of gold and copper. A little gold ore was shipped to the East Helena smelter from the Klondyke mine.

Mitchell district.—High-grade gold ore (21 tons) was produced from the Last Chance mine near East Helena.

Whitehall district.—The Golden Sunlight property was the third-largest gold producer in Montana in 1944. Marvin Reibhoff operated the property throughout the year and shipped 15,047 tons of highly siliceous gold ore to the Anaconda copper smelter at Anaconda. The ore is sufficiently high in silica for use as converter flux at the smelter. Lessees operated the Carbonate and Perhaps mines in 1944 and shipped 1,042 tons of lead ore to the East Helena lead smelter; both properties are owned by the Anaconda Copper Mining Co. The remainder of the district output was principally 424 tons of gold ore shipped from the Lucky Hit mine and 183 tons of lead ore from the Surprise and Minerva properties.

Wilson and Ticer Creeks district.—High-grade gold ore (81 tons) was produced from the Callahan group and shipped to a smelter.

JUDITH BASIN COUNTY

Barker district.—Thorson and Brazee purchased in 1944 part of the holdings (including the Edwards mine) of the St. Joseph Lead Co. in the Barker district. During the year the partnership shipped 44 tons of lead ore and clean-up material to the East Helena smelter.

Yogo district.—Walter Lehman operated the Gold Bug mine a short time in 1944 and shipped 55 tons of gold ore to a smelter.

LEWIS AND CLARK COUNTY

Hobbsville district.—The value of the metal production in the Hobbsville district was 16 percent greater than in 1943. The Mike Horse mine, one of the chief producers of zinc and lead in Montana, is operated continuously in 1944 by the Mike Horse Mining & Milling Co. The company treated 57,767 tons of zinc-lead-copper concentrates and 2,591 tons of zinc concentrates. The mine and mill were operated at a capacity consistent with the available manpower. The Swansea Mines, Inc., completed erecting a 75-ton flotation mill at the Carbonate mine in 1944 and began milling operations in August. During the rest of the year a total of 2,713 tons of lead ore was treated in the mill, making 197 tons of lead concentrates. In addition, 7 tons of crude lead ore were shipped to a smelter.

Helena district.—The output of the Helena district was small lots of ore shipped to smelters from the Copper Cliff, Victory, and Krug properties. The placer output has been negligible since the closing in August 1943 of Porter Bros. bucket dredge.

Marysville district.—Martin Bros. treated about 3,000 tons of lead ore in 1944 from the Earthquake and Shakopee mines in its 35-ton flotation mill; the Montana Rainbow Mining Co. operated its Drum-Common mine and shipped 2,191 tons of siliceous gold ore to the East Helena lead smelter; and a lessee worked the Belmont mine and shipped 59 tons of gold ore to various smelters. The rest of the district production was 5 tons of zinc-lead ore from the Enterprise mine.

Missouri River district.—The Perry-Schroeder Mining Co. operated a dredge, equipped with 6-cubic foot buckets, on the Missouri River from January 1 to April 12, when all operations ceased. A total of 77,600 cubic yards of gravel was washed in 1944, yielding gold, silver, and a small amount of platinum and osmium. In its 1944 report the company states that operations stopped owing to exhaustion of dredge ground at Eldorado Bar.

Bimini district.—The most important producer, by far, in the Bimini district in 1944 was the Armstrong Syndicate, which operated the Armstrong property under lease and shipped 3,647 tons of lead ore to East Helena and 58 tons of zinc-lead ore to the Midvale (Utah) concentrator. The rest of the district output was principally 205 tons of lead ore shipped from property operated by the South Dakota Mining Associates and 81 tons of gold ore produced from the Clementh mine.

Smelter district.—The most important zinc producer and one of the leading lead producers in Montana in 1944 was the Anaconda slag-fuming plant at East Helena, owned and operated by the Anaconda Copper Mining Co. The plant was in continuous operation, except for short periods resulting from the closing for repairs of the East Helena lead blast furnace. The bulk of the slag treated in 1944 was current hot slag from the East Helena lead smelter; this slag resulted from the smelting of ores, concentrates, and zinc-smelter (electrolytic) lead residues. A total of 233,948 tons of current hot slag and cold slag was fumed and produced zinc-lead fume; however, the slag plant is credited only with 187,988 tons of slag fumed and the zinc-lead fume produced therefrom. The difference in slag fumed and products derived is credited to those mines which shipped to the East Helena lead smelter ores or concentrates that contained at least 6 percent zinc.

The American Smelting & Refining Co. resmelted 12,018 tons of old silver-copper-lead slag in 1944, and the Anaconda Copper Mining Co. shipped several thousand tons of zinc-smelter (electrolytic) lead residues to the Tooele (Utah) lead smelter.

LINCOLN COUNTY

Libby district.—The Standard Silver Lead Mining Co. operated its 60-ton flotation mill from May 1 to November 18—20 days on Snowshoe mine ore and the remainder on old tailings. A total of 4,700 tons of zinc-lead ore and old tailings was treated, making 155 tons of zinc-lead concentrates and 125 tons of zinc concentrates. In addition, 309 tons of zinc-lead ore were shipped direct to the East Helena lead smelter. The remainder of the district output was 11 ounces of placer gold recovered from the Comet and Liberty claims.

Troy or Grouse Mountain district.—The Big Eight mine was operated under lease about 60 days in 1944 by the Chance Mining Co. The company shipped 30 tons of zinc-lead ore to the East Helena smelter and 267 tons of similar ore to custom concentration mills in Utah.

MADISON COUNTY

McCarthy Mountain district.—Herman Mueller operated the Polly Jane mine and shipped 198 tons of lead ore to various smelters.

Norris and Norwegian district.—The output from the Norris and Norwegian district in 1944 was 469 tons of gold ore shipped to smelters and came from the Boaz, Lincoln, Emperor, and East Revenue mines; the Boaz contributed 447 tons of the total. The mine was operated from January 1 to October 1 by the Boaz Mining Co.; thereafter it was turned over to lessees.

Pony and South Boulder district.—The only output in the Pony and South Boulder district in 1944 was 36 tons of clean-up material from the Mammoth mill and 13 tons of gold ore from the Raspberry mine.

Rochester district.—Hatfield and Jacobson operated the Calvin mines throughout 1944 under lease and shipped 1,355 tons of zinc-lead ore to the Tooele (Utah) lead smelter. Camilla Gage operated the Emma mine and shipped 129 tons of lead ore to the East Helena lead smelter and 100 tons of zinc-lead ore to the Midvale (Utah) concentrator. Other production from the district was 56 tons of lead ore from the Jack Rabbit and Ajax mines.

Sheridan district.—In 1944 the Toledo-Buckeye property near Sheridan was an important producer of silver, lead, and zinc. The Victoria Mines, Inc., operated the property throughout the year and treated 32,785 tons of zinc-lead ore in its 120-ton Victoria flotation mill near Silverstar, compared with 20,438 tons in 1943. The Bureau of Mines, through its exploratory drilling program, revealed in 1944 important reserves of zinc-lead ore in the Toledo-Buckeye group, which are now being exploited. The remainder of the district output was principally 3,240 tons of low-grade gold-copper ore shipped to a smelter from the Dictator mine.

Silver Star district.—About 100 tons of rich gold ore from the Stella mine were shipped to a smelter, and small lots of zinc ore and lead ore from the Mary Lou claim were shipped to the Midvale (Utah) plant.

Tidal Wave district.—The output of the Tidal Wave district in 1944 comprised several classes of ore shipped to smelters; most of it was

4 tons of copper ore from the Johnston and Moffet groups and 19 tons of lead ore from the Inspiration mine.

Virginia City district.—Walter H. Myers took over the U. S. Grant mine and began operations July 1. During the remainder of 1944 a total of 1,756 tons of gold-silver ore was shipped to the Washoe Sampling Works. Some gold-silver ore from the Lone Star waste dump and some mill cleanings (gold) from the old Marietta mill also were shipped.

Washington district.—A little gold ore was produced and shipped from the Snowslide mine.

MEAGHER COUNTY

Castle Mountain district.—Lessees worked at the Cumberland waste dump and shipped 108 tons of lead-silver ore to the smelter at East Helena.

MINERAL COUNTY

Keystone district.—E. G. Smith reopened the Nancy Lee mine under lease agreement and made a test mill run of 1,303 tons of zinc-lead ore from the Silver Crescent mill near Wallace, Idaho.

Packer Creek district.—The Hecla Mining Co. operated the Silver Cable mine under lease from April 1 to November 18, 1944; the property is inaccessible during the winter months owing to heavy snowfall. During the year the company hauled 11,286 tons of zinc-lead ore from the mine to its flotation mill at Burke, Idaho. The ore yielded 55 tons of lead concentrates and 2,696 tons of zinc-lead concentrates.

MISSOULA COUNTY

Coloma district.—The only output in the Coloma district in 1944 was 7 tons of gold ore shipped from the Mammoth group and 3 tons of copper ore produced from the Josephine mine.

Wallace district.—A lessee operated the Hidden Treasure mine and shipped 212 tons of silver ore to the Washoe Sampling Works.

PARK COUNTY

New World district.—The McLaren Gold Mines Co. operated the Estelle-New Year's Gift group of properties throughout 1944 and treated 21,352 tons of gold ore in its 100-ton flotation mill, which yielded 779 tons of copper concentrates containing 3,857 ounces of gold, 4,985 ounces of silver, and 205,988 pounds of copper. The Emma mine produced a total of 626 tons of zinc-lead ore, of which 126 tons were shipped to East Helena, and the rest was shipped to the Anaconda zinc concentrator for treatment.

Sheepwater district.—The Jardine Mining Co. operated its Jardine mine continuously in 1944 and its 400-ton combination flotation-cyanide-amalgamation mill 11 months. The mill began operating February 1, and during the year a total of 50,430 tons of gold-arsenic ore was treated and yielded 5,879 ounces of gold and 1,526 ounces of silver in bullion and 693 tons of gold concentrates containing 1,264 ounces of gold, 416 ounces of silver, and a little copper; in addition to these metals, the operation yielded arsenic trioxide.

POWELL COUNTY

Nigger Hill district.—Hopkins & Sons Mining Co. produced the bulk of the output in the Nigger Hill district in 1944. The company mined a total of 1,493 tons of ore from the Charter Oak mine, of which 1,481 tons were zinc-lead ore treated in the company 50-ton flotation mill and 9 tons silver ore shipped to a smelter. The milling ore yielded 7 tons of lead concentrates and 39 tons of zinc concentrates. The remainder of the district output was nearly all zinc-lead-silver ore produced from the Lilly group.

Pioneer district.—The output of the Pioneer district comprised 1 ton of lead-silver ore from the Lois claim and 56 ounces of placer gold cleaned up from former dredging operations.

RAVALLI COUNTY

Curlew district.—The Hamilton Victor Mining & Milling Co. operated the Curlew mine near Victor throughout 1944 and its 70-ton flotation mill the first 9 months; the mine was developed during the last quarter of the year with favorable results. The mill treated 4,170 tons of gold-silver-copper-lead-zinc ore, recovering 91 tons of lead-copper concentrates and 95 tons of zinc concentrates.

SANDERS COUNTY

Camas Prairie district.—In 1944 a lessee continued to operate the Glaucus mine and shipped 233 tons of copper ore to a smelter.

Eagle district.—All the ore mined in 1944 from the Jack Waite property, which extends over the State line into Idaho, came from that portion within Montana. The property was operated throughout the year by the American Smelting & Refining Co. and produced 9,770 tons of zinc-lead ore containing 10,649 ounces of silver, 2,209,974 pounds of lead, and 304,824 pounds of zinc. The ore was milled in the company-owned 300-ton flotation mill at Duthie, Idaho; 1,334 tons of lead concentrates and 214 tons of zinc concentrates were produced. Sorted lead ore shipped to a smelter amounted to 161 tons and contained 915 ounces of silver and 260,313 pounds of lead.

Revais Creek district.—The Green Mountain Mining Co. operated the Drake property near Dixon and shipped 25 tons of high-grade copper ore to a smelter.

SILVER BOW COUNTY

The value of the metal output of Silver Bow County was \$38,877,303 in 1944 compared with \$42,100,656 in 1943—an 8-percent loss. The output of gold, silver, and copper decreased, whereas that of lead and zinc increased. The gain in production of lead and zinc resulted principally from an increase in output of zinc-lead ore from the Poulin mine at Butte. Although the Anaconda Copper Mining Co. (only active major producer in the county in 1944) treated a greater quantity of copper material than in 1943, the total content in gold, silver, and copper was less. The increased tonnage and decreased metal content resulted from the treatment of a greater portion of mine dumps and waste tailings. The only zinc ore produced on company account, aside from the zinc-lead-middling product made from the

treatment of manganese ore, was extracted in the course of development or exploration in the company zinc mines. The following table gives the output of mines in Silver Bow County (which includes the Butte or Summit Valley district) in 1943 and 1944 and the total from 1882 to the end of 1944.

Production of gold, silver, copper, lead, and zinc in Silver Bow County, Mont., 1943-44, and total, 1882-1944, in terms of recovered metals

Year	Mines producing	Ore (short tons)	Gold (lode and placer) (fine ounces)	Silver (lode and placer) (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value

² Short tons.

Butte or Summit Valley district.—The following operational details are taken in part from the Anaconda Copper Mining Co. printed annual report for the year ended December 31, 1944.

The company operations in Montana in production, reduction, and processing of metals were curtailed by a critical shortage of manpower in practically all departments. No important construction program was undertaken at any of the company plants in Montana during 1944. The aggregate tonnage of copper mine ore, dumps, waste tailings, and slimes treated exceeded that in 1943 by 4 percent. The copper concentrator at Anaconda treated 2,362,041 tons of copper ore from company-owned Butte mines compared with 3,197,206 tons in 1943; and 3,706 tons of copper mine-water precipitates were treated compared with 3,582 tons in 1943. In addition, the copper concentrator at Anaconda treated 1,387,782 tons of New Works sand tailings compared with 812,513 tons in 1943 (in both years the tailings averaged about 0.6 percent copper); 752,571 tons of mine dumps averaging about 0.8 percent copper) compared with 404,359 tons in 1943; 125,372 tons of special waste compared with 88,314 tons in 1943; and 4,364 tons of Old Works tailings compared with 372,049 tons in 1943. Crude ore from the Butte mines amounted to 67,642 tons and special waste 1,936 tons.

The slime-disintegrating plant, with a daily rated capacity of 2,000 tons, treated slimes in 1944 as follows: 279,007 tons of Butte and Boston slimes, 207,133 tons of New Works Valley Pond slimes, and 28,340 tons of Old Works slimes; the 514,480 tons of slimes treated averaged 1.36 percent copper. In 1943 the plant treated 13,816 tons of slimes from all sources. The zinc concentrator was utilized for a dual purpose in 1944. The crushing and grinding equipment was used for treatment of copper mine dumps from Butte. After being ground to flotation size, one-fourth of the total dumps material was floated in a 14-cell flotation machine at the zinc concentrator; the rest was sent to the copper concentrator for treatment. The remainder of the feed to the zinc concentrator was a sulfide middling concentrate from manganese ore.

The Anaconda Copper Mining Co. operated the property of the North Butte Mining Co. throughout 1944 under contract agreement. The output from the property was 130,113 tons of copper mill ore and 126 tons of copper mine-water precipitates compared with 100,368 and 176 tons, respectively, in 1943. A total of 1,181 tons of zinc ore was mined from all company zinc mines incident to exploration and development. Development at all company copper mines consisted of 687 feet of shaft, 191,712 feet of drifts, and 5,182 feet of diamond-drill holes; at all company zinc mines, 1,706 feet of drifts and 199 feet of diamond-drill holes. The Emma mine was operated throughout 1944 by the Anaconda Copper Mining Co. under lease agreement. Production totaled 21,644 tons of zinc-lead middlings (from the treatment of manganese ore). In addition, 3,487 tons of zinc-lead middlings were produced as a byproduct from the milling of manganese ore from the Travona mine; all middlings were treated in the Anaconda zinc concentrator. Development comprised 13,872 feet of drifts in the Emma mine and 4,862 feet of drifts and 143 feet of diamond-drill holes in the company-owned manganese mines.

Lessees of the Anaconda Copper Mining Co. operated several properties at Butte in 1944 and produced about 16,700 tons of ore; the most productive was the Poulin mine, which yielded 15,284 tons of zinc-lead ore containing about 500 ounces of gold, 80,000 ounces of silver, 167,000 pounds of copper, 1,130,000 pounds of lead, and 4,500,000 pounds of zinc. The remainder of the district output was mainly 13,786 tons of material (containing chiefly silver and lead) shipped direct to the East Helena lead smelter from the Alloy dump.

Smelter district.—The Domestic Manganese & Development Co. treated manganese ore from mines principally in the Butte and Flint Creek (Philipsburg) districts in 1944. This ore was from current mine production as well as from the Metals Reserve Company stock pile at Philipsburg and comprised both oxide and sulfide minerals. A zinc-lead-middling product (26,084 tons) was made as a byproduct; this was separated into a zinc-lead concentrate (850 tons) and a zinc concentrate (319 tons).

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEVADA

(MINE REPORT)

By CHARLES WHITE MERRILL

SUMMARY OUTLINE

	Page		Page
Summary	389	Mining industry	393
Estimation of value of metal production	389	Ore classification	394
Production by counties	393	Metallurgic industry	394
		Review by counties and districts	399

SUMMARY

The quantity and value of zinc produced in Nevada in 1944 were the highest in the history of the State. Lead output was the highest in quantity and value since 1941. The total value of gold, silver, copper, lead, and zinc recovered from ore, old tailings, and gravels in Nevada, however, decreased 3 percent compared with 1943 because of smaller outputs of copper, gold, and silver. Higher wages, enlistment of miners in the armed forces, migration of miners to war industries and military construction jobs, rising prices of supplies and equipment and difficulties in obtaining them, increased taxes, and fixed prices for gold and silver were factors in reducing the total output, despite Nevada's great mineral resources and the war demand on many of them. The continued enforcement of War Production Board Order L-208 of October 8, 1942, was also a factor in the lowered output of gold mines. Grants to operate under the order were given eight companies during 1944, and seven grants issued in 1943 continued in force.

Comparing 1944 with 1943, gold output decreased 18 percent and silver 22 percent in both quantity and value; copper decreased 14 percent in quantity and 11 percent in value; lead increased 38 percent in quantity and 47 percent in value; and zinc increased 52 percent in quantity and 60 percent in value. Of the total value of the five metals, copper comprised 61 percent, zinc 17, gold 15, lead 4, and silver 3 percent.

White Pine County continued its lead over the other counties and produced 62 percent of the State total value of the five metals; it stood first in output of copper and of gold and second in silver and zinc. Lincoln County produced 20 percent of the State total value and ranked second to White Pine County; it led in the State in zinc, lead, and silver.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Yardage figures used in measuring material treated in placer operations are "bank measure"; that is, the material is measured in the ground before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.06
1941.....	35.00	0.711+	.118	.057	.07
1942.....	35.00	0.711+	.121	.067	.09
1943.....	35.00	0.711+	.130	.075	.10
1944.....	35.00	0.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Company for overquota production.

⁴ \$0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Nevada, 1940-44, and total, 1859-1944, in terms of recovered metals

Year	Mines producing ¹		Ore, old tailings, etc. (short tons)	Gold (lode and placer)		Silver (lode and placer)

¹ Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

² Compiled by Chas. W. Henderson, Metal Economics Division, Bureau of Mines. From 1904 (when first satisfactory annual canvass of mine production was made) to 1944, inclusive, the output was as follows: Gold, 13,507,179.51 ounces valued at \$320,770,403; silver, 298,896,832 ounces, \$201,815,894; copper, 1,679,531 tons, \$475,104,660; lead, 295,939 tons, \$34,967,605; zinc, 303,382 tons, \$45,027,050; total value, \$1,077,665,512.

³ Figures not available.

⁴ Short tons.

Gold.—Gold production in Nevada in 1944 was the lowest in quantity and value since 1933. Although the recession in gold began after the large output of 1940, monthly production did not assume a marked downward trend until August 1942. By February 1943 a much lower level had been established, which has persisted with minor fluctuations through 1944. This period of sharp decline included the weeks when War Production Board Limitation Order L-208, promulgated October 8, 1942, was taking effect.

The 10 leading gold-producing mines in 1944 supplied 94 percent of Nevada's output, and the 3 leaders contributed 70 percent. The curtailment of gold mining and the stimulation of base-metal mining is evidenced by the fact that byproduct gold from base-metal mines

1943 and 1944 exceeded gold derived from gold mines for the first time in the history of the State.

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc and total value in Nevada, 1860-1944.

Ten leading gold-producing mines in Nevada in 1944, in order of output

Mine	District	County	Rank in 1943	Operator	Source of gold
Gatchell	Potosi	Humboldt	2	Gatchell Mine, Inc.	Gold ore.

Consolidated Virginia	do	do	18	Consolidated Virginia Mining Co.	Gold-silver ore.
Mirpah	Tonopah	Nye	10	Various lessees	Do.

Silver.—The 10 leading silver-producing mines in Nevada in 1944 produced 70 percent of the State total recoverable silver; the first yielded 33 percent of the total. As in preceding years, most of the silver was a byproduct of ore mined chiefly for other metals; only 6 percent of it was derived from straight silver ore. Base-metal ores were the source of 81 percent of the State silver in 1944.

Ten leading silver-producing mines in Nevada in 1944, in order of output

Copper.—Over 96 percent of the recoverable copper output of Nevada in 1944 came from mines operated by the following companies: The Kennecott Copper Corp. (Nevada Mines Division), working the Ruth mine at Ruth and the open pit at Copper Flat (both in the Robinson district, White Pine County); the Consolidated Coppermines Corp., working the Coppermines group at Kimberly (also in the Robinson district); and the Mountain City Copper Co., working the Mountain City mine at Mountain City (in the Cope district, Elko County). During 1944 the Kennecott Copper Corp. and the Consolidated Coppermines Corp. reached an agreement to extend the former company's open pit so as to mine ore belonging to the latter; preparatory stripping of overburden was under way at the end of 1944.

Lead.—Over 61 percent of the lead produced in Nevada in 1944 was mined in the Pioche district, Lincoln County, where the leading lead properties were: The Pioche Nos. 1 and 2 group operated by the Combined Metals Reduction Co., the Ely Valley mine operated by Ely Valley Mine, the Prince mine operated by the Prince Consolidated Mining Co., and the Financier mine operated by the Salt Lake-Pioche Mining Co. and lessees. Other important producers in the State were: The Bristol Silver Mines Co. Bristol Silver mine (Jack Rabbit district, Lincoln County), the Coronado Copper & Zinc Co. Yellow Pine mine (Yellow Pine district, Clark County), the Nevada Lead & Zinc Co. (Spruce Mountain district, Elko County), the International Mining Corp. Groom mine (Groom district, Lincoln County), and Hall Bros. Co., Inc., Tybo mine (Tybo district, Nye County).

Zinc.—In 1944, as in recent years, zinc production in Nevada was centered in the Pioche district, Lincoln County, where 87 percent of the State total for the year was mined. The Combined Metals Reduction Co., Prince Consolidated Mining Co., and Ely Valley Mine were the principal producers. Other important producers in the State outside the Pioche district were: Sam Robison Columbia mine (Robinson district, White Pine County), Coronado Copper & Zinc

Yellow Pine mine (Yellow Pine district, Clark County), Grand Deposit Mining Co. Grand Deposit mine (Aurum district, White Pine County), Bristol Silver Mines Co. Bristol Silver mine (Jack Rabbit district, Lincoln County), and Union Lead Mining & Smelting Co. Union Lode mine (Galena district, Washoe County).

MINE PRODUCTION BY COUNTIES

The production of gold, silver, copper, lead, and zinc in Nevada in 1944, by counties, in terms of recovered metals

County	Mines producing ¹		Gold						Silver (lode and placer)	
	Lode	Placer	Lode		Placer		Total		Fine ounces	Value

¹Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

²Output from property not classed as a "mine."

MINING INDUSTRY

The 18-percent decline in total tonnage of ore and old tailings sold or treated in Nevada in 1944 compared with 1943 reflects a decline in copper ore output slightly greater than the decline in all ores taken together. The smaller copper-ore production resulted from a

chronic labor shortage throughout the State which grew progressively more acute as the year passed.

The connected-bucket dredge of the Manhattan Gold Dredging Co. in the Manhattan district, Nye County, was again the largest producer of placer gold and was fifth-largest of total gold in the State.

Except for this operation, Nevada placer mines were virtually quiescent.

ORE CLASSIFICATION

The following table classifying ores produced in Nevada in 1944 shows that 90 percent of the tonnage (including old tailings) sold or treated was copper ore and old tailings, 5 percent gold ore and old tailings, 3 percent zinc ore, and the remainder gold-silver ore, zinc-lead ore and old tailings, lead ore, and silver ore.

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in Nevada in 1944, with content in terms of recovered metals

¹ Includes 9,245,700 pounds of copper from precipitates.

² Includes 8,865,300 pounds of copper from precipitates.

METALLURGIC INDUSTRY

Of the 6,863,505 tons of lode material from Nevada mines sold or treated during 1944, 91 percent went to concentrating mills, 6 percent to amalgamation and cyanidation mills, and 3 percent to smelters; of the total, 0.07 percent was old tailings—all cyanided or smelted. Flotation was employed to the exclusion of gravity methods at concentration mills. Of the gold recovered as bullion, cyanidation supplied 98 percent and amalgamation 2 percent; of the silver recovered as bullion, 94 percent was derived by cyanidation and 6 percent by amalgamation. The tonnage of crude ore and old tailings shipped to smelters increased 20 percent compared with 1943.

The 500-ton selective-flotation mill operated by the Combined Metals Reduction Co. at Pioche, Lincoln County, treated zinc-lead and zinc ores upon a custom basis for several neighboring mines and also milled company zinc-lead ore. The mill's capacity was increased

1,000 tons daily during the year. The Kennecott Copper Corp. mined all the copper ore produced by the Consolidated Coppermines Corp. upon a contract basis, in addition to milling its own ore. The Kennecott Copper Corp. also operated the McGill copper smelter, Nevada's only smelter and the most important privately financed metallurgical plant in the State.

CHURCHILL COUNTY

Fairview district.—Lowell Thompson shipped lead ore to a smelter from the Chalk Mountain mine during 1944.

CLARK COUNTY

Yellow Pine (Goodsprings) district.—The Argenta Consolidated Mining Co. worked the Argenta mine throughout 1944; 607 tons of zinc ore containing 5 ounces of gold, 3,767 ounces of silver, 1,527 pounds of copper, 51,991 pounds of lead, and 247,577 pounds of zinc were shipped to a smelter; in addition, the company shipped 1,310 tons of oxidized zinc ore to the Metals Reserve Company stock pile at Jean. The Diamond Gold Mining Co. and Jay Jacobson worked the Green Monster mine during 1944 and shipped to a smelter 152 tons of zinc-lead ore containing 323 ounces of silver, 408 pounds of copper, 29,623 pounds of lead, and 59,414 pounds of zinc; in addition, 2,800 tons of oxidized zinc ore containing approximately 20 percent zinc and 3 percent lead were shipped to the Metals Reserve Company stock pile at Jean. The Root Zinc Lease worked the Root Zinc mine throughout 1944; 119 tons of zinc ore containing 426 ounces of silver, 109 pounds of copper, 8,783 pounds of lead, and 74,407 pounds of zinc were shipped to a smelter; in addition, 350 tons of oxidized zinc ore were shipped to the Metals Reserve Company stock pile at Jean. T. J. Hammond and R. H. Reed shipped zinc-lead ore to a smelter from the Seabiscuit mine during 1944. L. F. Jacobson worked the Sultan mine during 1944; 1,042 tons of zinc-lead ore containing 7 ounces of gold, 9,884 ounces of silver, 1,380 pounds of copper, 196,520 pounds of lead, and 437,309 pounds of zinc were shipped to a smelter; in addition, 705 tons of oxidized zinc ore were shipped to the Metals Reserve Company stock pile at Jean. The Coronado Copper & Zinc Co. shipped zinc ore, zinc-lead ore, and zinc-lead old tailings from the Yellow Pine mine during 1944.

ELKO COUNTY

Contact (Salmon River) district.—The Marshall Mining Co. shipped copper ore from the Delano and Allen mines during 1944. E. A. Yadon, a lessee, operated the Queen of the Hills mine from May 30, 1944, until the end of the year; 179 tons of copper ore containing 194 ounces of silver and 28,772 pounds of copper were shipped to a smelter.

Cope (Mountain City) district.—The Mountain City Copper Co. (again the third-largest copper producer in Nevada) was active throughout 1944; part of the ore was treated in the company 400-ton flotation mill, and high-grade copper ore was shipped for direct smelting.

Delano district.—The American Smelting & Refining Co. worked the Cleveland mine from January 1 to December 31, 1944, when operations were terminated because development had failed to yield expected results; substantial shipments of lead ore were made to the company Murray smelter during the year. C. E. Roak shipped lead ore to a smelter from the Gold Note mine during 1944. Tooley & McDonley worked the Net mine from January 1 to September 30, when labor shortage forced suspension of the operation; 599 tons of lead ore containing 6 ounces of gold, 9,358 ounces of silver, 562 pounds of copper, and 176,037 pounds of lead were shipped to a smelter.

Merrimac district.—The Rip Van Winkle Consolidated Mining Co. treated the Rip Van Winkle mine from January 1 to November 1, 1944. Inability to obtain labor resulted in suspension of the operation. Lead ore was treated in the company 100-ton flotation mill, and lead concentrate and zinc concentrate were shipped to smelters.

Redwood district.—L. D. Foreman & Co. shipped material from the Redwood slag dump to a lead smelter during 1944.

Spruce Mountain district.—Silver ore was shipped to a smelter by the Missouri Monarch Consolidated Mines Co. from the Blackfoot mine during 1944. Eugene Parker operated the Humbug mine and shipped 113 tons of lead ore containing 325 ounces of silver, 147 pounds of copper, and 28,691 pounds of lead to a smelter during the year.

ESMERALDA COUNTY

Divide district.—The Tonopah Divide Mining Co., through lessees, operated the Tonopah Divide mine throughout 1944; 1,195 tons of ore containing 800 ounces of gold and 3,040 ounces of silver were shipped to a smelter.

Silver Peak district.—Fred Vollmar shipped gold ore to a smelter from the Mary mine during 1944.

EUREKA COUNTY

Cortez district.—Joe McCarthy operated the Majestic (Mill Canyon) mine owned by the Roberts Mining & Milling Co. and treated gold-silver ore by flotation. Lead concentrate and zinc concentrate were shipped to a smelter.

Eureka district.—The Callahan Zinc-Lead Co. carried on a development campaign at the Mount Hope mine throughout 1944; 2,757 tons of zinc ore were shipped to the Combined Metals Reduction Co. Bauer mill in Utah, where 241 tons of lead concentrate containing 16 ounces of gold, 3,822 ounces of silver, 76,788 pounds of lead, and 2,174 pounds of zinc and 288 tons of zinc concentrate containing 1 ounce of gold, 555 ounces of silver, 4,782 pounds of lead, and 306,956 pounds of zinc were recovered. In addition the company stock-piled ore for treatment when its 200-ton flotation mill, moved from Arizona and under construction at the new site during the year, is ready for operation. The Mountain View Mining Co. operated the Mountain View mine throughout 1944 and shipped 279 tons of zinc ore containing 18,964 pounds of lead and 184,305 pounds of zinc to a smelter. The Eureka Corporation, Ltd., was engaged in developing the Richmond-Eureka mine throughout 1944; old speiss, treated principally for arsenic but yielding also gold, silver, copper, and lead, was shipped to a smelter.

HUMBOLDT COUNTY

Awakening district.—Austin Bros. Gold Mining Co. treated gold ore from the Jumbo mine by amalgamation during 1944.

Potosi district.—Gatchell Mine, Inc., treated gold ore from the Gatchell mine in a 1,000-ton cyanide plant. The arsenic content of the ore, which had required installation of expensive roasting equipment, proved most welcome when War Production Board Order L-208 went into effect because this property was permitted to continue operations as a producer of strategic arsenic. The company tungsten production program was terminated on June 20, 1944.

LANDER COUNTY

Battle Mountain district.—The International Smelting & Refining Co. operated its 350-ton flotation mill at the Copper Canyon mine throughout 1944. In addition to copper concentrates, crude copper ore and old tailings were shipped to smelters. Lessees worked the Copper Queen mine throughout the year; 1,123 tons of copper ore containing 6 ounces of gold, 148 ounces of silver, and 55,093 pounds of copper were shipped to a smelter. Hogle Bros. worked the Nevada mine from January 1 to June 30 and shipped 220 tons of lead ore containing 50 ounces of gold, 3,097 ounces of silver, 332 pounds of copper, 86,126 pounds of lead, and 5,171 pounds of zinc to a smelter. Symanzik & Wrobel worked the Trinity mine throughout 1944; 1,558 tons of silver ore containing 133 ounces of gold, 29,433 ounces of silver, 3,107 pounds of copper, and 134,590 pounds of lead and 310 tons of lead ore containing 28 ounces of gold, 9,115 ounces of silver, 531 pounds of copper, and 48,514 pounds of lead were shipped to a smelter.

Bullion district.—Willow Creek Mines, Inc., worked the Goldacres mine throughout 1944. Ore mined by open-pit methods was treated at the company 300-ton cyanide mill.

McCoy district.—Johnson & Uren worked the Gold Dome mine and shipped 177 tons of ore containing 233 ounces of gold, 163 ounces of silver, and 400 pounds of copper to a smelter.

New Pass district.—Smith & Snyder worked the Thomas W. mine throughout 1944 and amalgamated 200 tons of ore which yielded 107 ounces of gold and 17 ounces of silver.

LINCOLN COUNTY

Comet district.—Comet Mines, Inc., worked the Comet mine from January 1 to December 12; 1,071 tons of gold-silver ore treated by flotation yielded 21 tons of zinc-lead concentrate containing 19 ounces of gold, 867 ounces of silver, 454 pounds of copper, 5,573 pounds of lead, and 7,662 pounds of zinc. In addition, 100 tons of lead ore containing 39 ounces of gold, 1,546 ounces of silver, 430 pounds of copper, and 22,454 pounds of lead were shipped for direct smelting.

Groom district.—The International Mining Corp. worked the Groom mine from April 15 to December 31; 1,146 tons of ore containing 3 ounces of gold, 6,040 ounces of silver, and 461,960 pounds of lead were shipped to a smelter. The company 50-ton flotation mill was idle because of the labor shortage.

Jack Rabbit district.—The Bristol Silver Mines Co. shipped zinc-lead ore and copper ore to smelters during 1944.

Pioche district.—The Combined Metals Reduction Co. operated its 500-ton flotation mill on company and custom ore throughout 1944. This mill's capacity was expanded and reached 1,000 tons of ore daily at the end of the year; however, labor shortages at the mines supplying ore resulted in some of the new capacity remaining unutilized. Company ore for the mill was derived from the Abe Lincoln, Amalgamated Pioche, Pioche 802 and Raymond Ely West mines, also called the Pioche Nos. 1 and 2 group. Mill products were lead concentrate and zinc concentrate which were shipped for further treatment. In addition to company-produced ore the Combined Metals Pioche mill treated 72,544 tons of zinc ore mined by Ely Valley Mine and a smaller quantity of zinc ore mined by the Prince Consolidated

Mining Co.—The Salt Lake-Pioche Mining Co. worked the Apex and Financier mines throughout 1944; 1,062 tons of silver ore containing 31 ounces of gold, 36,028 ounces of silver, 333 pounds of copper, and 74,378 pounds of lead were shipped to a smelter from the Apex mine. In addition, 130 tons of lead ore containing 8 ounces of gold, 8,758 ounces of silver, and 15,771 pounds of lead were shipped. The production from the Financier mine, which was leased to Free Bros., totaled 1,175 tons of lead ore containing 113 ounces of gold, 46,130 ounces of silver, 427 pounds of copper, and 382,587 pounds of lead. The Queen Mining Co. shipped 270 tons of gold-silver ore containing 59 ounces of gold, 2,116 ounces of silver, 1,878 pounds of copper, and 15,606 pounds of lead from the Highland Queen mine before inability to hire miners forced a suspension of operations.

LYON COUNTY

Yerington district.—During 1944 lessees working the Mason Valley mine shipped 3,920 tons of copper ore containing 22 ounces of gold, 983 ounces of silver, and 389,592 pounds of copper. Angelus Basic Copper shipped 1,568 tons of copper ore containing 11 ounces of gold, 313 ounces of silver, and 110,718 pounds of copper from the Northern Lights mine. Western Nevada Mining Co. shipped 2,347 tons of copper ore containing 15 ounces of gold, 515 ounces of silver, and 121,998 pounds of copper from the Western Nevada mine. The International Smelting & Refining Co. continued its exploration and development campaign at the Gelder property during the year; no production was reported.

NYE COUNTY

Manhattan district.—Lessees operated the Manhattan mine from May 1 to December 31. The Manhattan Gold Dredging Co., only large producer of placer gold in the State in 1944, operated a connected-bucket dredge from January 1 to March 14 and from July 25 to December 31 under grant by the War Production Board. The dredge was equipped with 108 $9\frac{1}{4}$ -cubic foot buckets.

Tonopah district.—Several sets of lessees worked parts of the Tonopah Mining Co. of Nevada property throughout 1944 and shipped gold-silver ore to a smelter. The West End Consolidated Mines Corp. shipped 665 tons of gold-silver ore containing 108 ounces of gold and 9,259 ounces of silver to a smelter from the West End mine.

Tybo district.—Hall Bros. Co., Inc., worked the Tybo group of mines throughout the year and shipped lead ore and zinc-lead ore for treatment at smelters and custom flotation plants.

Union district.—L. D. Foreman & Co. shipped dump ore and old slag from Downeyville to a smelter.

PERSHING COUNTY

Antelope (Majuba) district.—Greenan-Kerr Tin Mine shipped to a smelter 13,575 tons of copper ore containing 117 ounces of gold, 22,358 ounces of silver, 1,081,430 pounds of copper, and 1,901 pounds of lead.

Arabia district.—Lessees operating the C. W. and G. D. B. mine shipped to a smelter 142 tons of lead ore containing 4 ounces of gold, 1,346 ounces of silver, 108 pounds of copper, and 34,080 pounds of lead.

Seven Troughs district.—Earl Tucker treated ore by amalgamation at the Portland mine.

STOREY COUNTY

Comstock district.—The Virginia City Mining Co. operated the Consolidated Virginia mine from March 27 to August 26, 1944, and shipped gold-silver ore to a cyanide mill for treatment. A small quantity of gold and silver was recovered during a mill clean-up carried on by the Sutro Tunnel Coalition, Inc., at the Crown Point and Yellow Jacket mines. The Central Comstock Mines Corp. operated its 100-ton countercurrent cyanide plant from September 10 to November 1 on ore mined at the Savage, Hale and Norcross, Chollar, and Potosi mines.

WASHOE COUNTY

Galena district.—The Union Lead Mining & Smelting Co. treated ore from the Union Lode mine by jig concentration and flotation and shipped gold-silver concentrates, lead-copper concentrates, and zinc concentrates to smelters and to custom concentrators for selective flotation.

White Horse (Olinghouse) district.—Lessees treated 12 tons of ore by amalgamation at the Texas No. 2 lode mine and recovered 65 ounces of gold and 24 ounces of silver.

WHITE PINE COUNTY

Aurum (Silver Mountain) district.—The Grand Deposit Mining Co. operated the Grand Deposit mine throughout 1944 and shipped 1,118 tons of copper ore containing 14 ounces of gold, 4,178 ounces of silver, 93,535 pounds of copper, and 8,050 pounds of lead; 38 tons of lead ore containing 1 ounce of gold, 196 ounces of silver, 400 pounds of copper, and 5,358 pounds of lead; and 2,492 tons of zinc ore containing 4 ounces of gold, 1,292 ounces of silver, 33,213 pounds of copper, 43,836 pounds of lead, and 897,840 pounds of zinc. During July all the surface equipment was destroyed by fire, but reconstruction was nearly complete at the end of the year.

Robinson (Ely) district.—The Nevada Mines Division of the Kennecott Copper Corp. worked the Copper Flat pit and the Ruth mine throughout 1944. This corporation also operated the McGill flotation concentrator (daily capacity, 20,000 tons) and the McGill copper smelter, both at McGill, where the product of its mines and that of the Consolidated Coppermines Corp. were treated. This company, largest privately financed industrial organization in Nevada, was the leading producer of copper in the State and stood second in production of gold and silver. The Consolidated Coppermines Corp., second-largest copper and third-largest gold producer in the State in 1944, was active throughout the year. Operations by both companies were severely curtailed by labor shortage. Sam Robison shipped to a smelter from the Columbia mine 3,867 tons of zinc ore containing 63 ounces of gold, 7,669 ounces of silver, 19,063 pounds of copper, 151,321 pounds of lead, and 1,236,060 pounds of zinc. L. D. Foreman & Co. shipped material from the King old slag dump. W. M. and H. T. Farnsworth shipped gold-silver ore and lead ore from the Monarch mine.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN NEW MEXICO

(MINE REPORT)

By RICHARD H. MOTE

SUMMARY OUTLINE

	Page		
Summary.....	407	Mining industry.....	411
Calculation of value of metal production.....	408	Ore classification.....	412
Mine production by counties.....	411	Metallurgical industry.....	412
		Review by counties and districts.....	415

SUMMARY

New Mexico zinc production was larger in quantity in 1944 than in any previous year except record-making 1943, and output of lead was the largest in quantity since 1935. However, except for 1943, gold production was the lowest since 1880 and silver since 1926. Although the output of copper was less than in 1943, it was greater than in any year prior to 1940.

Comparing 1944 with 1943, gold increased 24 percent and silver 15 percent in both quantity and value; lead increased 27 percent in quantity and 35 percent in value; copper decreased 8 percent in quantity and 5 percent in value; and zinc decreased 15 percent in quantity and 10 percent in value. The total value of the five metals was 5 percent less than in 1943; and, of the total, copper represented 38 percent, zinc 36, lead 4, and silver and gold each 1 percent.

FIGURE 1.—Value of mine production of copper and zinc and total value of gold, silver, copper, lead, and zinc in New Mexico, 1870-1944. The value of gold, silver, and lead produced annually has been relatively small.

Grant County continued to be the largest contributor to the metal-mining output of New Mexico; it produced 92 percent of the State total value and stood first in the output of each of the 5 metals. Socorro County produced 4 percent of the State total value and ranked second to Grant County in production of lead and zinc. Hidalgo County contributed 3 percent and was second to Grant County in production of gold, silver, and copper. Of the 10 counties producing

in New Mexico in 1944, these 3 furnished over 99 percent of the State total value of the 5 metals.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ⁴	Zinc ⁵
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940.....	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063
1941.....	35.00	¢.711+	.118	.057	.075
1942.....	35.00	¢.711+	.121	.067	.093
1943.....	35.00	¢.711+	.130	.075	.108
1944.....	35.00	¢.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+(\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Company for overquota production.

⁴ \$0.7111111.

The following table shows the number of mines in New Mexico producing gold, silver, copper, lead, and zinc and their annual output of ore and metals from 1940 to 1944, as well as the total production from 1848 to 1944. The report of this series for 1929 (chapter of Mineral Resources of the United States, 1929, pt. 1, pp. 729-759) gives the yearly production of each important metal-producing district in New Mexico from 1904 to 1929, inclusive. Subsequent records year by year may be found in annual issues of Mineral Resources and Minerals Yearbook.

Mine production of gold, silver, copper, lead, and zinc in New Mexico, 1940-44, and total, 1848-1944, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value

Gold.—Mine production of recovered gold in New Mexico increased from 5,563 fine ounces in 1943 to 6,918 ounces in 1944. The principal gold-producing districts in 1944 were: Central, Grant County, which produced 34 percent of the State output of recovered gold; Lordsburg, Hidalgo County, 33 percent; Mogollon, Catron County, 15 percent; Willow Creek (Terrero), San Miguel County, 8 percent; Steeple Rock, Grant County, 4 percent; Pinos Altos, Grant County, 3 percent; and Magdalena, Socorro County, 2 percent. Copper ore yielded 37 percent of the State total gold; zinc-lead ore, 33 percent; dry and siliceous ores, 21 percent; and lead and zinc ores, 9 percent. The principal producers in 1944, in order of output, were as follows: The Banner Mining Co. in Hidalgo County, United States Smelting, Refining & Mining Co. (Bullfrog mine) in Grant County, Silver Creek Mining Co. in Catron County, Atwood mine in Hidalgo County, Terrero Mining Co. (Pecos mine) in San Miguel County, New Mexico Ore Processing Co. (Peerless mine) in Grant County, Boston Bicket mine in Grant County, Exploration Syndicate, Inc. (Carlisle mine) in Grant County, and Kennecott Copper Corp. (Chino mine) in Grant County; these five properties produced 90 percent of the State total output of gold.

Silver.—Mine production of recovered silver in New Mexico increased from 463,583 fine ounces in 1943 to 535,275 ounces in 1944. The Central district contributed 40 percent of the State total in 1944; Lordsburg, 21 percent; Magdalena, 12 percent; Mogollon, 11 percent; Steeple Rock, 4 percent; Pinos Altos, 3 percent; Willow Creek (Terrero), 2 percent; Kingston, 2 percent; and Swartz, 2 percent. Zinc-lead ore yielded nearly 63 percent of the total silver; copper ore, nearly 22 percent; dry and siliceous ores, 12 percent; and lead and zinc ores, 4 percent. The following 10 producers, in order of output, contributed 81 percent of the State total: The United States Smelting, Refining & Mining Co. (Bullfrog mine) in Grant County, American Smelting & Refining Co. (Ground Hog Unit) in Grant County, Silver Creek Mining Co. in Catron County, Atwood mine in Hidalgo County, Banner Mining Co. in Hidalgo County, American Smelting & Refining Co. (Magdalena Unit) in Socorro County, New Mexico Ore Processing Co. (Peerless mine) in Grant County, Peru Mining Co. (Copper Flat, Kearny, and Pewabic mines) in Grant County, Exploration Syndicate, Inc. (Carlisle mine) in Grant County, and Empire Zinc Co. (Kelly mine) in Socorro County.

Copper.—Mine production of recovered copper in New Mexico in 1944 was 139,460,000 pounds, a decrease of 8 percent from 1943. The Chino open-pit mine of the Kennecott Copper Corp. at Santa Rita.

Grant County, continued to be by far the largest copper producer in the State; the second-largest continued to be the Banner Mining Co., south of Lordsburg, Hidalgo County; and other substantial producers (in order of output) were the Burro Mountain group of the Phelps Dodge Corp. at Tyrone, Grant County, and the Stauber mine near Pastura, Guadalupe County. Copper ore and precipitates from mine water and leached dumps yielded 99 percent of the total copper; virtually all the remainder was recovered from concentrates produced by the milling of lead, zinc, and zinc-lead ores.

Lead.—Substantial gains in production of lead in the Central district, Grant County, and the Magdalena district, Socorro County, were responsible for the increased lead output in New Mexico in 1944. Lead production from the Central district was the largest in the history of the district, and production from the Magdalena district was the largest since 1917. Grant County contributed 71 percent of the State total lead in 1944; Socorro County produced 22 percent. Four properties—the American Smelting & Refining Co. Ground Hog (ranking first in output) and Magdalena (third) Units, the United States Smelting, Refining & Mining Co. Bullfrog mine (second), and the New Mexico Ore Processing Co. Peerless property (fourth)—produced 60 percent of the total output during the year. Zinc-lead ore yielded over 89 percent of the total lead; lead ore, more than 9 percent; copper ore, 1 percent; and zinc ore and dry and siliceous ores, less than 0.5 percent.

Lead concentrates produced in 1944 amounted to 12,025 tons containing, as shipped, 1,397 ounces of gold, 219,902 ounces of silver, 927,591 pounds of copper, 12,137,352 pounds of lead, and 1,879,763 pounds of zinc; the average lead content was 50.47 percent.

Zinc.—Nearly 91 percent of the total recovered zinc produced in New Mexico in 1944 came from Grant County; virtually all the remainder came from the Magdalena district, Socorro County. The principal producers in 1944, in order of output, were the United States Smelting, Refining & Mining Co. (Bullfrog mine), Peru Mining Co. (Copper Flat, Kearny, and Pewabic mines), Empire Zinc Co. (Hanover mine group), and American Smelting & Refining Co. (Ground Hog Unit), all in the Central district, Grant County; American Smelting & Refining Co. (Magdalena Unit), Magdalena district, Socorro County; Black Hawk Consolidated Mines Co. (Hobo mine), Central district, Grant County; Empire Zinc Co. (Kelly mine), Magdalena district, Socorro County; and New Mexico Ore Processing Co. (Peerless mine), Central district, Grant County. Zinc-lead ore yielded 98 percent of the total zinc, and the remaining 2 percent came from zinc ore.

Zinc concentrates produced in 1944 amounted to 107,556 tons compared with 127,748 tons in 1943. The metal content, as shipped, was 1,073 ounces of gold, 133,031 ounces of silver, 1,097,167 pounds of copper, 2,442,940 pounds of lead, and 117,084,131 pounds of zinc. The average zinc content of concentrates was 54.43 percent in 1944 compared with 53.70 percent in 1943.

MINE PRODUCTION BY COUNTIES

Production of gold, silver, copper, lead, and zinc in New Mexico in 1944, by counties, in terms of recovered metals

MINING INDUSTRY

The metal-mining industry of New Mexico was encumbered in 1944 by the hectic conditions accompanying the Nation's third year of World War II. The most significant factor affecting the production of metals was the desperate shortage of manpower. During the latter part of the year this shortage was more critical than at any time since the entry of the United States into the war. Even more serious than the lack of skilled labor was the inability of the industry to conduct mining and development simultaneously. Several operators found it advisable to curtail their efforts to meet war demands for peak pro-

duction in favor of development programs to assure adequate ore reserves for future operations. Absenteeism continued to hamper the major producers, for even under the most favorable underground working conditions it was reported as high as 20 percent. The withdrawal of deferments of young mine workers pointed to a greater need for manpower at the battle fronts, a sharp contrast to 1943 when soldiers were returned to the mines to augment the dwindling labor supply.

The general policy of the Quota Committee pertaining to the premium-price plan for overquota production of domestic copper, lead, and zinc as revised in 1943 prevailed throughout 1944. The latter part of the year found the producers increasingly apprehensive over the continuance of premiums on these three metals. Specific concern was evident over the 30-day cancellation clause of all except the basic A premium.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in New Mexico in 1944, with content in terms of recovered metals

Source	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore.....	182	395	284	1,400	1,750	-----

	7,941,581	5,444	472,440	139,451,116	14,515,907	101,454,000
Total, lode mines.....	7,943,846	6,910	535,275	139,460,000	14,530,000	101,454,000
Total, placers.....	-----	8	-----	-----	-----	-----
	7,943,846	6,918	535,275	139,460,000	14,530,000	101,454,000
Total, 1943.....	8,329,043	5,563	463,583	152,326,000	11,448,000	119,048,000

¹ Includes 23,936,645 pounds of copper recovered from precipitates from mine water and leached dumps.

² Includes 27,744,537 pounds of copper recovered from precipitates from mine water and leached dumps.

METALLURGIC INDUSTRY

Of the 7,943,846 tons of ore mined in 1944 in New Mexico, 7,850,208 tons (99 percent) were treated at concentration plants, and 93,638 tons (1 percent) were shipped crude to smelters. Copper ore sold or treated decreased from 7,571,937 tons in 1943 to 7,207,554 tons in 1944, zinc ore from 361,391 to 6,332, and dry and siliceous ores from 2,916 to 2,265; zinc-lead ore increased from 392,153 to 723,418, and lead ore from 586 to 4,277 tons.

Flotation was employed at all concentrating mills; of the ore (7,850,208 tons) treated, 7,120,423 tons were copper ore, 723,418 tons zinc-lead ore, 6,257 tons zinc ore, and 110 tons lead ore. Flotation mills in operation during the year were: Chino at Hurley; Empire

East Hanover; Hanover Unit near Hanover; Bullfrog near Vancou-
 ver; Banner near Lordsburg; Peru near Deming; Magdalena Unit
 near Magdalena; Continental at Silver City; Southwestern near
 Tucson, Ariz. (operating on ore from the Carlisle group in the Steeple
 Rock district, Grant County); and East Camp at Steeple Rock. The
 reverberatory smelter of the Kennecott Copper Corp. at Hurley
 was operated throughout 1944 on company copper concentrates,
 precious copper ore, and copper precipitates recovered from leaching
 waste dumps. Copper precipitates from company operations at
 Silver City, Ariz., were treated also. Most of the copper produced at the
 smelter in 1944 was marketed in the form of fire-refined copper bars.
 The Exploration Syndicate, Inc., completed conversion of the East
 Camp cyanide mill to selective flotation (daily capacity, 125 tons) in
 September. Before conversion of the mill, ore was treated at the
 Northwestern Minerals Co. mill at Duncan, Ariz.

In March the New Mexico Ore Processing Co. purchased the Con-
 tinental Chemical & Ore Co. mill at Silver City. The new owners
 increased the capacity of the plant from 60 tons per day to 100, built
 a new assay office and metallurgical laboratory, and installed addi-
 tional ore bins.

*Mine production of metals in New Mexico in 1944, by methods of recovery, in terms
 of recovered metals*

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

¹ Includes copper recovered from precipitates.

CATRON COUNTY

Mogollon district.—The Silver Creek Mining Co. operated the Eureka mine throughout 1944 and shipped 1,862 tons of dry gold-silver ore containing 1,069 ounces of gold, 61,349 ounces of silver, and 1,129 pounds of copper to the El Paso smelter.

DONA ANA COUNTY

Organ district.—The Hornspoon and Nellie Bly mines were operated during the latter part of 1944 by the B-3-M Corp.; 12 tons of ore containing 180 ounces of silver, 414 pounds of copper, and 1,324 pounds of lead were shipped to El Paso for smelting.

GRANT COUNTY

Burro Mountain (Tyrone) district.—Throughout 1944 the Phelps Dodge Corp. continued leaching operations at its Burro Mountain mine. Water is percolated through the subsided areas of the former mine workings, and copper is precipitated from the return solutions. The copper content of the leach water and the production of precipitates continued to decline in 1944. L. Yacomo and Marvin Fuller continued production from the Contact group of claims until April 1, 1944; 833 tons of zinc-lead sulfide ore were shipped to the Hanover Unit custom mill.

Central district (Bayard, Fierro, Georgetown, Hanover, Santa Rita).—The Chino Mines Division of the Kennecott Copper Corp., largest copper producer in New Mexico, operated its open-pit mine at Santa Rita and its flotation mill and reverberatory copper smelter at Hurley at approximate capacity throughout 1944. The manpower shortage became so critical during the latter part of the year that on October 16 the company was forced to reduce operations to a 6-day week. Copper continued to be recovered by leaching accumulated dump material from the pit and from siliceous copper ore used in the converters as a flux. Molybdenum, gold, and silver are recovered in the concentration mill as byproducts. Most of the copper produced in 1944 was marketed in the form of fire-refined copper bars. The company continued development of its Oswaldo and Ivanhoe zinc properties in the Central district. Zinc-lead ore from the Oswaldo property was treated in the Empire Zinc Co. mill at Hanover.

Despite a 14-percent decrease in production of recovered zinc compared with 1943, the Central district continued to be the fourth-largest zinc-producing district in the United States. The largest producer of zinc in the Central district in 1944 was the Bullfrog mine and 450-ton selective-flotation mill of the United States Smelting, Refining & Mining Co., which operated continuously during the year. Lead concentrates produced were shipped to the El Paso smelter; zinc concentrates were shipped to the Dumas (Tex.), Fort Smith (Ark.), and Great Falls (Mont.) reduction plants. Development at the Bullfrog property included 4,284 feet of drifts, 733 feet of raises, 19,563 feet of diamond drilling, and 455 feet of shaft sinking. The company conducted an intensive drilling program in the district on the many claims it owns or holds under option; 13 core-drilling machines were in operation during the year. The Peru Mining Co. continued to operate its Pewabic, Copper Flat, and Kearny mines.

from the mines is treated at the company 1,000-ton selective-flotation mill at Wemple near Deming (Luna County).

The Empire Zinc Co. operated its Hanover mine group and selective-flotation mill continuously in 1944. In addition to ore from the company properties in the Central district, the mill treated ore from the company Lynchburg and Kelly mines at Kelly, Socorro County, and the Oswaldo mine of the Kennecott Copper Corp. in the Central district.

The American Smelting & Refining Co. continued to operate its Ground Hog Unit (Ground Hog, Lucky Bill, and San Jose claims) and released Hanover milling unit (formerly Combination-Black Hawk) throughout 1944. Crude lead ore shipped to the El Paso smelter was produced from the Denver claim. Development at the Ground Hog mine included 8,939 feet of drifts and 36,088 feet of diamond drilling. The mine is developed by a three-compartment vertical shaft to the 600-foot level and then an inclined winze extending to the 1,000-foot level. The Hanover milling unit operated at capacity (400 tons per day) throughout the year. In addition to company ore from the Ground Hog mine, the mill treated custom ore (comprising 5 percent of the total mill feed) from the Hobo, Barringer (September), Peerless, and Three Brothers mines in the Central district; the Columbus, Grandview, Royal John, and Patsy mines in the Swartz (Carpenter) district; the Cleveland and Houston-Thomas properties in the Pinos Altos district; the Contact mine in the Burro Mountain (Tyrone) district; the Hornet mine in the Eureka district; the Ruth mine near Lordsburg; the Percha mine near Kingston; the Nitt and Blue Stone properties at Kelly; and the Tom Payne mine near Cerrillos.

The Black Hawk Consolidated Mines Co., largest custom ore shipper to the Hanover milling unit, operated its Hobo mine throughout the year; 41,190 tons of zinc-lead sulfide ore were milled. Important developments at this property in 1944 were the sinking of the Hobo shaft from 300 feet to 400 feet and the opening of Hobo shaft No. 2 to the 100-foot level; 947 feet of drifts also were completed. The New Mexico Ore Processing Co. continued to operate its Peerless mine in the Central district and did development on several claims in the Pinos Altos district. Zinc-lead sulfide ore from the company properties was treated in the Continental 100-ton selective-flotation mill at Silver City (purchased from the Continental Chemical & Ore Co. in March 1944). Several shipments of ore were made to the El Paso smelter from the Little Goat, Boston Bicket, and Mike mines.

Eureka district.—The Mineral Production Co. operated the Hornet property intermittently during 1944; 218 tons of zinc-lead ore containing 2,283 ounces of silver, 829 pounds of copper, 26,226 pounds of lead, and 33,515 pounds of zinc were shipped to the Hanover Unit custom mill. M. J. Fowles shipped 1 car of lead ore to the El Paso smelter from the American claim.

Pinos Altos district.—R. R. Foster, W. R. Jenks, and Douglas White, lessees, operated the Cleveland mine throughout 1944 and made regular shipments of zinc-lead ore to the Hanover Unit custom mill. B. O. Shepherd shipped zinc-lead ore to the Hanover mill from his Houston-Thomas mine. Lead ore was shipped to the El Paso smelter from the Cleveland, Houston-Thomas, and Hardluck properties.

Steeple Rock district.—The Exploration Syndicate, Inc., continued to lease and operate the Carlisle group of mines. Before conversion of the East Camp cyanide mill to selective flotation (completed in September) the Carlisle ore was treated at the Southwestern Minerals Co. mill at Duncan, Ariz. In addition to conversion of the East Camp mill, the company completed 650 feet of drifts and 7,000 feet of exploratory diamond drilling in 1944. In November, Carl Elayer and K. C. Richmond leased the Center claim; 46 tons of dry gold ore containing 22 ounces of gold, 113 ounces of silver, 1,371 pounds of copper, and 457 pounds of lead were shipped to the El Paso smelter.

Schwartz (Carpenter, Camp Monarch) district.—The Black Range Development Co. operated the Columbia, Grandview, and Patsy mines throughout the year; 4,496 tons of zinc-lead ore were shipped to the Hanover Unit custom mill. Zinc-lead ore totaling 2,324 tons was shipped also to the Hanover mill from the Royal John mine, operated by A. L. Owen.

GUADALUPE COUNTY

The Guadalupe Mining Co. continued to operate the Stauber mine near Pastura. Siliceous copper ore totaling 8,864 tons and containing 308 ounces of silver and 619,675 pounds of copper was shipped to the El Paso smelter.

HIDALGO COUNTY

Apache district.—E. J. Marston operated the Monarch and Copper Crown claims during the first half of 1944; 231 tons of lead ore shipped to the El Paso smelter contained 1 ounce of gold, 1,236 ounces of silver, 597 pounds of copper, and 55,171 pounds of lead.

Lordsburg district.—The Banner Mining Co. operated its Bonney mine and 500-ton flotation mill 6 miles south of Lordsburg continuously throughout 1944 on ore from the Lone and Shoofly claims. The company proceeded with development of the lower levels of the mine and sank the main shaft an additional 25 feet, giving it a total depth of slightly over 1,500 feet. The mill treated an average of 336 tons of ore per day; copper concentrates produced were shipped to the El Paso smelter. The Atwood group of claims on Atwood Hill near Valedon, 4 miles south of Lordsburg, was operated throughout the year by C. H. McIntosh. Shipments of siliceous copper ore to the El Paso smelter totaled 6,410 tons containing 641 ounces of gold, 57,811 ounces of silver, 354,897 pounds of copper, and 276,916 pounds of lead. Siliceous copper ore was shipped to the Miami (Ariz.) smelter from the Miser's Chest mine operated by Charles J. Hutchinson. The National Zinc Corp. made several shipments of zinc-lead sulfide ore from the Ruth mine to the Hanover Unit custom mill (Grant County). Other producing properties in the Lordsburg district were the Waldo, Tom group, and Anita mines.

San Simon (Steins) district.—J. H. Byrd worked the Crosby mine; 37 tons of lead ore containing 76 ounces of silver, 223 pounds of copper, and 7,374 pounds of lead were shipped to the El Paso smelter.

LUNA COUNTY

Deming district.—The Peru Mining Co. 1,000-ton selective-flotation mill at Wemple near Deming operated continuously during 1944 on

from the company Pewabic, Copper Flat, and Kearny mines near Silver (Grant County).

SAN MIGUEL COUNTY

Elbow Creek district (Terrero).—The Pecos mine, operated by the Pecos Mining Co. throughout 1944, produced copper, lead, and zinc which were shipped to smelters in Texas and Oklahoma.

SANTA FE COUNTY

Cerrillos district.—A. B. Stewart shipped 337 tons of zinc-lead sulfide ore from the Tom Payne mine, 8 miles north of Cerrillos, to the Hanover Unit custom mill during 1944. The Franklin Mines, Inc., and the Franklyn and Cash Entry mines north of Cerrillos from May 1 to June 1. A 25-ton experimental plant recovered 11 tons of lead concentrates containing 1 ounce of gold, 143 ounces of silver, 2 pounds of copper, and 12,196 pounds of lead. Considerable development and exploration of mining properties in the Cerrillos district were reported during the year.

SIERRA COUNTY

Chloride (Apache, Cuchillo Negro) district.—An operator on the Far Baby mine shipped 158 tons of dry silver ore to the El Paso smelter.

Kingston district.—The Percha mine on South Percha Creek west of Kingston was operated throughout 1944. Zinc-lead sulfide ore, totaling 1,087 tons and containing 28 ounces of gold, 14,341 ounces of silver, 36,916 pounds of copper, 120,817 pounds of lead, and 176,232 pounds of zinc, was shipped to the Hanover Unit custom mill (Grant County). A small lot of copper ore was shipped from the Copper King mine to the El Paso smelter.

• SOCORRO COUNTY

Magdalena district.—The American Smelting & Refining Co. continued to operate the Magdalena Unit (Waldo mine) and 200-ton selective-flotation mill during 1944. A shortage of mine labor and consequent reduction in ore output permitted the mill to operate only 6 days per week. Development completed during the year included 1,540 feet of drifts, 153 feet of winze, and 12,449 feet of diamond drilling. Concentrates produced were shipped to the Dumas (Tex.) smelter of the American Zinc Co. of Illinois and the El Paso smelter. Kenneth Hughes and J. D. Torres worked the Kelly Unit (Lynchburg and Kelly mines) under lease throughout the year and shipped zinc-lead ore to the Empire Zinc Co. selective-flotation mill at Hanover (Grant County). J. A. McDonald made regular shipments of zinc-lead ore from the Nitt claim to the Hanover Unit custom mill, to which also several cars of zinc-lead ore were shipped from the Blue Stone mine. Limited operations were carried on at the East Star and La Plata mines; several shipments of lead ore were made to the El Paso smelter.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN OREGON

(MINE REPORT)

By CHARLES WHITE MERRILL

SUMMARY OUTLINE

	Page		Page
Summary.....	420	Mining Industry.....	42
Calculation of value of metal production.....	421	Ore classification.....	42
Mine production by counties.....	423	Metallurgic Industry.....	42
		Review by counties and districts.....	427

SUMMARY

Gold production in Oregon in 1944, although 25 percent above the 1943 output, was less than 2 percent of the all-time record set just 4 years earlier (in 1940). Silver production nearly doubled in 1944 compared with 1943 but was otherwise the lowest since 1932. Copper output was the lowest since 1931; and lead production, which was very low, remained unchanged from 1943. No recovery of zinc has been reported since 1937.

The total value of the gold, silver, copper, and lead (in terms of recovered metals) produced in Oregon was \$63,760 in 1944, compared with \$48,038 in 1943 and with \$4,148,271 in the peak year 1940. It was divided among the metals as follows: Gold, 75 percent; silver, 23 percent; and copper and lead, 1 percent each. Jefferson County displaced Baker County in 1944 in total value of metal output, but the value of Baker County production was nearly as much.

Rising wages, enlistment of miners in the armed forces, migration of miners to war industries, rising costs of supplies and equipment and the difficulties of obtaining them, higher taxes, and a fixed price for gold and silver (principal metals produced in the State) were factors that continued to hold the mining industry near the low level that prevailed during 1943. Production, which had sunk to approximately one-third that in 1940, quickly collapsed when the War Production Board issued Order L-208 on October 8, 1942. All the larger gold, silver, copper, lead, and zinc mines had suspended operations before December 31, 1942, and none resumed work during 1943 or 1944.

Lode mines contributed 79 percent and placers 21 percent of the gold produced in Oregon in 1944. For a number of years before 1942, lode mines had produced about one-third and placers two-thirds of the gold output.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

Barrelage figures used in measuring material treated in placer operations are bank measure; that is, the material is measured in the barrel before treatment.

The value of metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940	\$35.00	\$40.711+	\$0.113	\$0.050	\$0.063
1941	35.00	4.711+	.118	.057	.075
1942	35.00	4.711+	.121	.067	.093
1943	35.00	4.711+	.130	.075	.108
1944	35.00	4.711+	.135	.080	.114

¹ Under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 31, 1937, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-44: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price of bonds payments by Metals Reserve Co. for overquota production.

⁴ Barrels.

Metal production of gold, silver, copper, lead, and zinc in Oregon, 1940-44, and total, 1852-1944, in terms of recovered metals

1944.....	10	30,200	293	10,255	.340

¹ Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

² Includes all placer operations using dragline excavator for delivering gravel to floating washing plant.

³ Gold from terminal clean-up; property and equipment not counted as producing.

⁴ Includes all placer operations using suction pump for delivering gravel to floating washing plant, except those producing less than 100 ounces of gold, which are included under "Small-scale hand methods"; no suction dredges reported for 1940.

⁵ Includes all placer operations using power excavator and washing plant, both on dry land; when washing plant is movable, outfit is termed "dry-land dredge."

⁶ Includes all operations in which hand labor is principal factor in delivering gravel to sluices, long toms, dip boxes, pans, etc.

⁷ A mine using more than 1 method of recovery is counted but once in arriving at total for all methods.

Gold.—The level of gold production in Oregon in 1943 and 1944 was lowest since 1902 and was probably the lowest since the years ending the discovery period in the 1850's. Placer mining was varied more than lode mining. Hydraulic, small-scale hand methods, and terminal clean-ups at idle plants where gravel had been mined mechanically accounted for the placer gold output in 1944. The lode gold came from siliceous ores, and most of this ore was mined chiefly for gold. There were 23 Oregon properties producing in 1944—13 lode mines and 10 placers; none produced as much as \$8,000 worth of gold.

Silver.—Silver production in Oregon in 1944 nearly doubled compared with 1943. Jefferson County yielded over 80 percent of the state total. Dry gold-silver ore was the principal source of silver and the direct smelting of ore the principal method of recovery.

Copper, lead, and zinc.—Copper production sank to 6,000 pounds, the lowest since 1931; lead output was 8,000 pounds, the same as in 1943 but otherwise the lowest since 1932. No zinc was reported recovered.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, and lead in Oregon in 1944, by counties, in terms of recovered metals

County	Mines producing ¹		Gold					
	Lode	Placer	Lode		Placer		Total	
			Fine ounces	Value	Fine ounces	Value	Fine ounces	Value
Clatsop	5	(?)	468	\$16,380	27	\$945	495	\$17,325

Wheeler	24	17					6,947
Total, 1944	20,243	14,395	6,000	810	8,000	640	63,700
	10,523	7,483	12,000	1,560	8,000	600	48,038

¹ Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

² Portion of property not classed as a "mine."

³ Combined to avoid disclosure of individual outputs.

⁴ Figures of total silver as follows—1944: 20,205 ounces from lode mines and 38 ounces from placers; 1943: 16,600 ounces from lode mines and 28 ounces from placers.

MINING INDUSTRY

Of the 4,217 tons of ore (including 1,000 tons of old tailings) sold or treated in Oregon in 1944, Baker County produced 2,488 tons or 59 percent and Jefferson County 1,561 tons or 37 percent. Over 6 percent of the total (including all the old tailings) was dry gold ore, and almost all the remainder was dry gold-silver ore.

No connected-bucket dredge, dragline dredge, or nonfloating washing plant, to which gravel was delivered by mechanical means was in production in 1944. However, final clean-ups at suspended operations resulted in the recovery of some gold, which is credited to nonfloating washing plants. The only consumption of quicksilver reported for Oregon placer mines in 1944 was at hydraulic operations, where 3 pounds were consumed, or 1 pound of quicksilver for each 33 ounces of gold recovered in 1944 compared with 1 pound of quicksilver for each 4 ounces of gold recovered at hydraulic operations in 1943.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore and old tailings sold or treated in Oregon in 1944, with content in terms of recovered metals

Source	Material sold or treated		Gold	Silver	Copper	Lead

METALLURGIC INDUSTRY

Of the State total ore and old tailings (4,217 tons), 42 percent was shipped crude to smelters; 26 percent (including all the old tailings) was cyanided; 22 percent was concentrated and the concentrates smelted; and 10 percent was amalgamated. Ultimate recovery of 65 percent of the total lode gold was from the smelting of ore, 20 percent was as bullion from the cyanidation of ore, 12 percent was as bullion from the amalgamation of ore, and 3 percent was recovered by the smelting of flotation concentrates. Nearly three-fourths of the silver was recovered by the direct smelting of ore and most of the remainder by the smelting of flotation concentrates. All material requiring smelting was shipped out of the State, as Oregon has no smelters. No data are available covering quicksilver or cyanide consumption at Oregon mills in 1944.

Production of metals in Oregon in 1944, by methods of recovery, in terms of recovered metals

¹ Only those counties and districts shown separately for which Bureau of Mines is at liberty to publish figures; others producing listed in footnote 6 and their output included under "Combined counties and districts."

² Excludes itinerant prospectors, snipers, high-graders, and others who gave no evidence of legal right to property.

³ Source of total silver as follows: 20,205 ounces from lode mines, 38 ounces from placers.

⁴ Output from a property not classed as a "mine."

⁵ Greenback district lies in both Jackson and Josephine Counties.

⁶ Includes following districts: Ashwood in Jefferson County; New Pine Creek in Lake County; and Grande Ronde in Union County.

BAKER COUNTY

Cracker Creek district.—Bald Mountain Mine operated the Bald Mountain mine throughout 1944; part of the gold ore produced was treated by amalgamation, and part was shipped to a smelter. Lessee worked the Columbia mine during 1944; 57 tons of ore containing 3 ounces of gold and 117 ounces of silver were shipped to a smelter, and 1,000 tons of old tailings cyanided yielded 145 ounces of gold and 84 ounces of silver.

Virtue district.—Anthony Brandenthaler shipped 898 tons of antimony ore from the Gray Eagle mine; the ore contained 212 ounces of gold, 76 ounces of silver, and 382 pounds of copper, in addition to antimony.

Weatherby district.—A. V. Lovejoy recovered 19 ounces of gold and 7 ounces of silver from 15 tons of ore produced at the Gleason mine.

CURRY COUNTY

Chetco district.—W. D. Bowser operated the Robert E. mine throughout 1944; 84 tons of ore cyanided yielded 64 ounces of gold and 11 ounces of silver, and 1 ton of ore shipped to a smelter contained 159 ounces of gold and 27 ounces of silver.

GRANT COUNTY

Granite district.—Bruce Dennis shipped from the Buffalo mine 23 tons of ore containing 110 ounces of gold, 900 ounces of silver, 152 pounds of copper, and 444 pounds of lead.

JACKSON COUNTY

Gold Hill district.—Lance Bros. hydraulicked 1,200 cubic yards of gravel at the Lance mine on Footh Creek and recovered 16 ounces of gold and 3 ounces of silver. Mardon Bros., largest gold producer in the State in 1943, amalgamated 1 ton of ore in 1944 from the Sunrise mine, from which 83 ounces of gold and 14 ounces of silver were recovered.

Upper Applegate district.—George Lewis hydraulicked 1,500 cubic yards of gravel at the Sterling mine and recovered 15 ounces of gold and 2 ounces of silver.

JEFFERSON COUNTY

Ashwood district.—The Oregon King mine was operated by E. Rohlfing until May 15, 1944, when the property was taken over by Henry Anderegg, who continued work until the end of the year. Gold-silver ore was treated in the company 50-ton flotation mill, and gold-silver concentrates were shipped to a smelter. In addition, gold-silver ore was shipped for direct smelting.

JOSEPHINE COUNTY

Seaback district.—M. H. Davis carried on a hydraulicking operation at the Blue Channel mine on Coyote Creek in 1944 from January to May 1.

UNION COUNTY

Pan de Ronde district.—The Union Silver Mining Co. shipped 28 tons of silver ore containing 976 ounces of silver, 144 pounds of copper, and 1,330 pounds of lead from the Indiana mine while carrying on development.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN SOUTH DAKOTA

(MINE REPORT)

By RICHARD H. MOTE

Calculation of value of metal production..	430	Metallurgic recovery.....	432
Mine production by counties.....	431	Review by counties.....	432

SUMMARY

South Dakota gold production in 1944 fell below that in any year since 1875—the year gold was discovered in the gravels of French Creek near the present site of Custer. Silver production was the lowest since 1876. Most of the gold produced during 1944 came from a thorough clean-up of equipment in connection with regular maintenance at the Homestake mill. The output of recovered gold in the State was 11,621 fine ounces valued at \$406,735, compared with 106,444 ounces valued at \$3,725,540 in 1943; in addition to gold, South Dakota in 1944 produced 5,445 fine ounces of silver, 2,000 pounds of recovered copper, 68,000 pounds of recovered lead, and 112,000 pounds of recovered zinc. No placer gold was produced in 1944.

All tonnage figures are short tons and “dry weight”; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.063
1941	35.00	¢.711+	.118	.057	.075
1942	35.00	¢.711+	.121	.067	.093
1943	35.00	¢.711+	.130	.075	.108
1944	35.00	¢.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Co. for overquota production.

¢ \$0.71111111.

MINING AND METALLURGIC INDUSTRY

Ore mined and treated at lode mines in South Dakota in 1944 totaled 2,839 tons yielding, in terms of recovered metals, 126 fine ounces of gold, 2,777 fine ounces of silver, 2,000 pounds of copper, 68,000 pounds of lead, and 112,000 pounds of zinc. Maintenance during the year at the Homestake property included a clean-up of all mill equipment, which recovered 11,495 ounces of gold and 2,661 ounces of silver. No gold-bearing material was treated by amalgamation or cyanidation during 1944.

¹ In terms of 96- to 98-percent strength.

² From 17,614 tons of crude ore treated by table and jig concentration.

³ Revised figures.

⁴ Includes 263,165 pounds of calcium cyanide (48- to 49-percent strength); all reduced to equivalent of 16- to 98-percent strength to conform with earlier use of figures for high-strength NaCN and KCN.

REVIEW BY COUNTIES

LAWRENCE COUNTY

Homestake mine.—Operations at the Homestake mine, owned and operated by the Homestake Mining Co. since 1877, consisted only of maintaining mine and mill property in adequate stand-by condition for immediate operation as soon as the gold-mine closing order is rescinded. During the course of maintenance all mill circuits and equipment were given a thorough cleaning, which recovered some gold bullion. No development was done by the company in 1944. The annual report of the general manager of the Homestake Mining Co. for the year ended December 31, 1944, says—

Operation of the mine was suspended during the entire year 1944 in accordance with Order L-208 of the War Production Board. This was the first full year since production began on July 12, 1878, in which no ore was mined nor milled.

launders, pipe lines, mill liners, and other machinery in the mills were thoroughly cleaned in the course of maintenance. Amalgam and precipitate recovered were treated and shipped. This accounts for the revenue amounting to \$2,591.29 from bullion during the year.

As there was neither production nor development during the year the reserve of shipped ore remains unchanged. It totals 19,005,835 tons, which includes 585 tons of broken ore in shrinkage stopes. * * *

Production of materials essential to the war effort continued in the machine shop and foundry with increasing output throughout the year. Volume of shipments was largest in the last 2 months of the year. * * *

The Homestake mine and plant have been maintained in excellent condition and are in readiness for operation.

Four hundred and sixty former employees have joined the armed forces.

Ore milled, receipts, and dividends, Homestake mine, 1940-44¹

Year	Ore milled (short tons)	Receipts for bullion product		Dividends
		Total	Per ton	
1940	1,433,737	\$19,014,767.73	\$13.2624	\$9,041,760
1941	1,499,988	19,529,080.70	13.0195	9,041,760
1942	1,276,138	17,068,437.84	13.3856	7,534,800
1943	183,246	3,628,507.33	19.8067	-----
1944	(²)	402,591.29	(²)	-----

¹ From 1936 to 1944, inclusive, this mine yielded bullion and concentrates that brought a net return of \$3,421,254 and paid \$149,805,802 in dividends.

² No ore milled; bullion product recovered in clean-up of launders, pipe lines, mill liners, and other machinery during course of mill maintenance.

Other mines.—The Belle Eldridge Gold Mines, Inc.—only metal mine operating in South Dakota in 1944 for production of gold, silver, copper, lead, or zinc—worked its group of claims and 50-ton selective-fotation mill in the Whitewood district during the first half of the year. Operations during the latter part of the year consisted of development of the zinc-lead ore reserves to augment the diamond-drilling program conducted by the Federal Bureau of Mines. Production came from the Helen Gould, Iris, and Horus claims. Lead concentrates assaying 1.28 ounces of gold and 27.9 ounces of silver per ton, 40.60 percent lead (wet assay), and 9.10 percent zinc were shipped to the Leadville (Colo.) smelter, and zinc concentrates assaying 0.0687 ounce of gold and 2.557 ounces of silver per ton, 1.05 percent lead (wet assay), and 49.00 percent zinc were shipped to the smelter at Amarillo, Tex. Development in 1944 consisted of 556 feet of drifts, 455 feet of tunnel, and 3,440 feet of diamond drilling.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN TEXAS

(MINE REPORT)

SUMMARY

Texas mines produced (in terms of recovered metals) 5,355 fine ounces of silver and 230,000 pounds of copper in 1944, having a total value of \$34,858, compared with 4 ounces of gold, 10,284 ounces of silver, 162,000 pounds of copper, and 26,000 pounds of lead in 1943, having a total value of \$30,463. The Hazel mine in Culberson County yielded over half the silver produced in 1944, and copper ore from the Black Shaft mine in Hudspeth County yielded the bulk of the copper. No gold or lead was recovered from ores mined in Texas in 1944; no zinc has been recovered since 1917.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³

SMELTING AND REFINING PLANTS IN TEXAS

The lead and copper smelters of the American Smelting & Refining Co. in El Paso operated continuously in 1944 and furnished a market for domestic ores and concentrates produced by operators in Arizona, Missouri, New Mexico, Texas, and Virginia and foreign ores and

concentrates from operators in Mexico, Argentina, Canada, Chile, Ecuador, South-West Africa, French Equatorial Africa, and Southern Rhodesia. During 1944 the lead smelter consisted of two blast furnaces having a total annual capacity of 250,000 tons of charge. The copper plant was equipped with two reverberatories, having a total annual capacity of 600,000 tons of charge, and three converters.

The American Smelting & Refining Co. gas-fired horizontal-retort zinc smelter at Amarillo operated throughout the year on zinc concentrates purchased from operators in Arizona, Colorado, New Mexico, Montana, Nevada, and South Dakota and in Mexico. Although the plant is equipped with eight furnaces having a total of 6,400 retorts, a continued shortage of skilled smelter labor during 1944 prevented the company from operating all the furnace blocks. The company electrolytic zinc plant at Corpus Christi, with an annual capacity of 29,000 tons of cathode zinc, operated throughout the year mostly on foreign concentrates, although producers near Hanover, N. Mex., furnished some tonnage.

The gas-fired horizontal-retort zinc smelter of the American Zinc Co. of Illinois at Dumas was operated throughout the year but approximately at half capacity because of the chronic manpower shortage and general quality of the available labor. This plant is equipped with eight furnaces having a total of 6,656 retorts. Concentrates were purchased from operators in Arizona, Colorado, Idaho, New Mexico, and Utah and in Mexico.

The Phelps Dodge Corporation electrolytic copper refinery at El Paso continued to treat blister copper anodes cast at the corporation smelters in Arizona. Part of the refinery product was in the form of fire-refined copper recovered from a portion of the output of the Morenci (Ariz.) copper smelter.

MINES REVIEW BY COUNTIES

Culberson County.—A. P. Williams continued to operate the Hazel mine near the Culberson-Hudspeth County boundary at the south end of the Sierra Diablo Range 14 miles northwest of Van Horn during the first few months of 1944 and shipped 326 tons of dry silver ore, containing 3,579 ounces of silver and 4,909 pounds of copper, to the El Paso smelter.

Hudspeth County.—The Black Shaft mine in the Carrizo Mountains 9 miles northeast of Allamore was operated throughout 1944 by M. F. Drunzer; a total of 3,799 tons of copper ore, containing 1,269 ounces of silver and 232,977 pounds of copper, was shipped to the El Paso smelter. Drunzer also made one small shipment of dry silver ore from the Sancho Panza property 7 miles northeast of Allamore. In the Sierra Blanca district, R. M. Clark did some development on the Bonanza mine in the Quitman Mountains 12 miles west of Sierra Blanca and constructed a small mill to treat an estimated 35,000 tons of dump ore averaging 5 percent zinc and 3 percent lead.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN UTAH

SUMMARY

Utah mines produced gold, silver, copper, lead, and zinc valued, in terms of recoverable metals, at \$111,036,247 in 1944, an 11-percent decrease from \$124,562,540 in 1943. The total value of these five metals in Utah exceeded that of every other State except Arizona. Utah remained the largest gold-producing State and was second in copper production. A smaller output of each of the five metals resulted in the decrease in total value, although the average prices paid for copper, lead, and zinc were higher than in 1943. Declines were general throughout the State, with the exception of zinc output from the Tintic district and gold production in Tooele County. The value of metal output in the Bingham district declined \$10,513,226 (10 percent) compared with 1943, the Park City region \$1,436,510 (20 percent), and the Tintic district \$911,142 (24 percent). The Utah Copper Co. continued to account for a major part of the value of Utah metal production and in 1944 contributed 77 percent of the total.

Utah metal mines were unable to produce a greater quantity of these metals during 1944 not only because of conditions that were inherent in the mining industry, such as failure in equipment, plant failure, and underground-mine flooding, but of those over which the industry had no control, among which the acute labor shortage was foremost. In 1943 the labor shortage had been alleviated somewhat by the use of soldiers furloughed from the Army, but during 1944 no such help was forthcoming. The shortage, as in other western mines, was the greatest single cause for the decline in output of all metals.

The extent and effect of the shortage can best be judged by the fact that at the end of 1943 a canvass of the major metal producers in the State showed a total of 9,417 employees on the pay roll, whereas these same properties at the end of 1944 showed a total of 7,689 employees, of whom only an average of 7,095 were at work. Absenteeism was epidemic among the major producers in 1944. A canvass at the end of 1944 indicated that the absenteeism average ranged from a high of 19 percent in underground mines to less than 1 percent under the most favorable working conditions; however, the absenteeism

averaged over 7 percent throughout the State. These shortages not only affected current production but limited necessary development to such a point that most underground mines in the State face a period of intense development and exploration before reserves are again normal.

Although most mines in the State were subject to almost monthly revision of quotas for the payment of premiums for overquota production, the general policy of the Government as set forth the latter part of 1943 prevailed throughout 1944. Premium payments to several mines were the only means of rendering continued operation possible, as operating costs had increased considerably beyond the net value of the metals produced, when calculated on the basis of the average market quotations.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

FIGURE 1.—Value of mine production of gold, silver, copper, lead, and zinc, and total value in Utah, 1870-1944.

Gold.—Utah was again the largest gold-producing State; however, the output was 344,223 fine ounces, a 12-percent decline from 390,470 ounces in 1943. Gold produced in Utah is derived principally from base-metal ores; in 1944, copper, zinc-lead, lead, zinc-lead-copper, and zinc ores furnished 94 percent of the total and siliceous ores the remainder. No gold was recovered from placer operations in 1944. Mines in the Bingham district, by far the most important gold-producing area in the United States now active, produced 312,493 ounces of gold, a decrease of 31,058 ounces compared with 1943. The loss in the district can be attributed to a smaller output from each of the major gold-producing mines in the district except the National Tunnel & Mines Co. operation; however, the gain from this operation was small. These losses in gold output resulted from a smaller tonnage of ore from each producing mine, as the gold content of the ore mined in 1944 remained substantially the same as in 1943. The Park City region was the second most important gold-producing area in the State in 1944 and produced 15,149 ounces compared with 19,559 in 1943. Most of the decrease was due to a decline at the New Park Mining Co. operations. The tonnage of ore mined was not only smaller than in 1943, but the emphasis was on zinc-lead ore at the expense of higher grade gold ores at the company's disposal. The Tintic district—source of most of the siliceous gold ore in normal times—produced 11,417 ounces in 1944, a decline of 11,053 ounces from 1943. Mines in Tooele County showed a slight increase

in gold output. Most of the siliceous ore produced in the State was used as reverberatory and converter flux. Gold production from the Utah Copper Co. was considerably less than in 1943; nevertheless the company was the leading producer in the State. It was followed by the United States & Lark mines at Bingham, the Mayflower mine at Keetley, the Tintic Bullion mine in the Tintic district, the Boston Consolidated property at Bingham, the Butterfield group of properties in the Bingham district, the National Tunnel & Mines Co. properties in the Bingham district, and the Geyser Marion property in the Camp Floyd district. These eight properties produced 96 percent of the State gold output.

Silver.—The output of recoverable silver in Utah in 1944 was 7,593,075 fine ounces compared with 9,479,340 ounces in 1943, a 20-percent decrease. The Bingham district remained the leading silver-producing area in the State and supplied 62 percent of the State output. However, the district production was 14 percent less than in 1943, owing chiefly to much smaller outputs from the Utah Copper Co. and the United States & Lark property. A 29-percent decline was noted in the output from mines in the Park City region, the second leading silver-producing area in the State. Although the Park Utah Consolidated Mining Co. operations showed a net gain in silver production, it was more than offset by substantial losses at the Silver King Coalition Mines Co. and the New Park Mining Co. properties. A decrease of 339,548 ounces at the Tintic Standard mine was the chief reason for the 31-percent decline in silver output from the Tintic district. Zinc-lead, zinc-lead-copper, zinc, and lead ores yielded 53 percent of the State silver, copper ore 34 percent, and siliceous ores the remainder. The Utah Copper Co. was again the leading silver producer in Utah and was followed by the United States & Lark, Park Utah Consolidated, Silver King Coalition, Mayflower, Tintic Standard, Chief No. 1, West Calumet, Harold dump, and Godiva mines. These 10 properties contributed 90 percent of the State total output of silver.

Copper.—The output of recoverable copper in Utah was 565,150,000 pounds in 1944 compared with 647,978,000 pounds in 1943, a 13-percent decrease. Although all the principal copper-producing operations except the National Tunnel & Mines Co. showed decreased output, the Utah Copper Co. showed by far the greatest. The Utah Copper Co. mined a total of about 66,000,000 tons of ore and waste, at the rate of $1\frac{1}{4}$ tons of waste to a ton of ore, in 1944 compared with about 80,000,000 tons in 1943. The operations at the open-pit mine at Bingham were continuous except for brief stoppages necessitated by the closing of the concentrating mills at Arthur and Magna. The copper content of the ore treated in 1944 was about the same as that treated during the previous year. Copper ore mined in Utah totaled 29,930,659 tons compared with 35,999,656 tons in 1943; the total value of gold, silver, copper, and lead recovered from copper ore and precipitates was \$87,401,850 in 1944, or 79 percent of the State value of all five metals. In addition, copper ore yielded a considerable quantity of molybdenum sulfide, exceeded only by the quantity recovered by the Climax Molybdenum Co. in Colorado.

All the Utah mines producing over 1,000,000 pounds of recoverable copper in 1944 are in the Bingham district and include the Utah Copper Co. (over 97 percent of State output), the National Tunnel

Mines Co. property, the Ohio Copper Co. property, and the United States & Lark mines.

Lead.—The output of recoverable lead in Utah in 1944 was 1,388,000 pounds, a 20-percent decrease from 1943. During the year the principal lead-producing mines in the State had the greatest shortage of labor ever experienced by them. This shortage, as well as stoppages due to other causes, and the fact that in June the mines began working one shift a day rather than two resulted in the lowest output of lead in the State since 1921. The Bingham district remained the principal lead-producing area, with an output of 62,337,000 pounds; however, this production represents a decrease from 1943 of 18,536,300 pounds in consequence of reduced output from all the principal producing properties except that of the Montana Bingham Consolidated Mining Co. The mines in the Park City region were the second leading source of lead in the State and produced 23,319,600 pounds, or 27 percent less than in 1943; each of the large producers in the district showed a decrease, of which the largest—about 5,900,000 pounds—was reported by the Silver King Coalition Mines Co. The Tintic district, third-largest source of lead in the State, produced 1,687,700 pounds, a decrease of 36 percent compared with 1943; the decline in output of this district was caused by a much smaller production from the Tintic Standard mine, which more than offset slight gains at the Chief Consolidated Mining Co. property. A considerable quantity of siliceous ore containing 3 to 4 percent lead was shipped from mines and tailings dumps in the Tintic district to be used as flux at copper smelters in the Salt Lake Valley. Recoverable lead from this source aided materially in counterbalancing the losses from lead properties in the district. The United States & Lark property in the Bingham district was by far the most important source of lead in the State. It was followed by the Park Utah Consolidated group, the Mayflower and Silver King Coalition mines in the Park City region, the West Calumet mine in Tooele County, the Chief Consolidated Mining Co. property and the Tintic Standard mine in the Tintic district, the Montana Bingham Consolidated group and the Butterfield group in the Bingham district, and the Harold dump in the Tintic district. These 10 properties produced 95 percent of the State total lead output.

Zinc.—The output of recoverable zinc from Utah mines was 77,988,000 pounds compared with 93,792,000 pounds in 1943, a 17-percent decrease. Decreases were noted in all the principal zinc-producing districts except the Tintic, from which production is comparatively small. The Bingham district showed a decline of 18 percent, caused principally by losses at the United States & Lark mines and the Butterfield group of properties. The principal zinc-producing mines in the Park City region, except the Park Utah Consolidated mine, reported decreases; however, the slight gain at the Park Utah Consolidated was insufficient to offset losses at the Silver King Coalition and New Park Mining Co. properties. The gain in zinc output from the Tintic district is attributed almost solely to the operation on the lower levels of the Chief No. 1 mine of the Chief Consolidated Mining Co., which contributed virtually all the zinc output of the district. All zinc and zinc-lead concentrates produced in Utah in 1944 were treated at the Anaconda and Great Falls (Mont.) zinc plants of the Anaconda Copper Mining Co. Zinc fume derived from the fum-

ing of current slag, cold slag, and crude ore was dealed and the shipped to Bartlesville, Okla., for further treatment. The United States & Lark property was the principal zinc producer in Utah in 1944. It was followed by the Tooele slag-fuming plant, the Park Utah Consolidated Mining Co. property, the Mayflower mine, the China No. 1 mine, the West Calumet mine, the Silver King Coalition mine, and the Butterfield group of properties. These eight properties furnished 96 percent of the State output of zinc.

MINE PRODUCTION BY COUNTIES

Mine production of gold, silver, copper, lead, and zinc in Utah in 1944, by county: in terms of recovered metals

County	Mines producing ¹	Ore (short tons)	Gold		Silver

¹ All lode mines in 1944; no placers operated in 1944, but 1 placer in 1943.

² Includes 4 ounces (\$140) of placer gold in Millard County.

MINING INDUSTRY

The production of copper ore dominates the mining industry in Utah, and in 1944 it represented 97 percent of the State total output of ores of all classes herein reported. The Bingham district produced

of all classes representing 98 percent of the State total. Of the 14,838 tons of ore of all classes produced from mines in the Bingham district, copper ore constituted 99 percent, and zinc-lead ore and siliceous ore nearly all the remainder. The grade of copper ore mined during the year was about the same as in 1943, but the zinc-lead ore was of a higher lead but lower zinc content. The bulk of ore produced from mines in the Park City region was zinc-lead ore, although substantial tonnages of zinc tailings were milled and siliceous tailings were shipped direct to smelters. The ore mined in the Park City region showed an increase in copper, lead, and zinc content compared with 1943. Zinc-lead ore for the first time was the chief product of metal mining in the Tintic district. Almost all the ore of this class came from the lower workings of the Chief No. 1 mine. There were substantial decreases in output of siliceous ore from mines in the Tintic district, and at least half of such ore came from mine dumps. The quantity of siliceous ore (available for smelters) that was mined throughout the State was much smaller than in 1943. The largest declines were noted in the Tintic district in Juab and Utah Counties and the Camp Floyd district in Tooele County; however, these two districts continued to supply most of the siliceous ore of the State.

The mining industry in Utah continued to receive considerable aid from various Government agencies. The Bureau of Mines gave much engineering assistance to both metal and nonmetal mines in 1944 and in addition assisted materially in exploring and developing many properties. The Grazing Service completed the construction of 173 miles of access roads to metal mines in Utah at an average cost of \$2157 per mile. The Reconstruction Finance Corporation continued its program of giving financial assistance to mines considered capable of producing needed minerals.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Utah in 1944, with content in terms of recovered metals

Source	Mines producing ¹	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Lead and siliceous gold ore.....	9	47, 410	10, 266	90, 075	946, 613	454, 503	-----

.....	4	97, 30, 940, 205	344, 223	7, 593, 075	2, 565, 150, 000	105, 038, 000	77, 988, 000
Total, 1943.....	111	37, 386, 731	390, 470	9, 479, 340	9, 647, 978, 000	130, 514, 000	93, 792, 000

¹All the mines in 1944; no placers operated in 1944, but 1 placer in 1943.

²Includes 35,936,977 pounds recovered from mine-water precipitates.

³Includes 6,890 tons of zinc slag.

⁴A mine producing more than 1 class of ore is counted but once in arriving at total for all classes.

⁵Includes 7,467,429 pounds recovered from mine-water precipitates.

METALLURGIC INDUSTRY

The mills, smelters, and slag-fuming plant in the Salt Lake Valley area represented the largest aggregation of custom reduction plants for complex ores in the United States. Custom milling capacity of the concentrating mills in the Valley area was about 3,800 tons of ore per day; of this total only about half was utilized in 1944.

In 1944 mines in Utah produced 30,940,205 tons of ore, treated as follows: 30,632,016 tons at concentrating mills, compared with 36,880,347 tons in 1943; 259,309 tons of ore shipped crude to smelters, compared with 397,342 tons in 1943; and 48,880 tons of slag fumed, compared with 109,042 tons in 1943.

Eleven concentrating mills were active in Utah during 1944; 5 of these plants (Arthur, Magna, Ohio Copper, Tooele, and Big Indian) treated 29,927,992 tons of copper ore and old tailings; 4 mills (Bauer, Midvale, Silver King, and Tooele), with a combined rated capacity of about 4,600 tons daily, treated 658,015 tons of ore (mostly lead, zinc-lead, zinc-lead-copper, and zinc); 1 gravity concentration mill treated 9 tons of silver ore; and 1 flotation mill in Summit County treated 46,000 tons of current zinc tailings. The 3 large custom milling plants—Midvale concentrator, Tooele concentrator, and Bauer concentrator—treated most of the zinc-lead, zinc-lead-copper, lead, and zinc ore milled in Utah in 1944. Each plant had available from company-owned mines the major part of the plant feed. Most of the feed for the Midvale concentrator came from the company-owned mines in the Bingham district, principally the United States & Lark mines; the greatest part of the mill feed at the Bauer mill came from company-owned mines in the Rush Valley and Bingham districts in Utah and the Triumph mine in Idaho; and the Tooele concentrator received most of its mill feed from the Park Utah Consolidated property in the Park City region. In addition to the ores received from mines in Utah, these mills received substantial quantities of ore from mines in California, Nevada, Colorado, Montana, Idaho, and Arizona. The Tooele concentrator at Tooele, owned and operated by the International Smelting & Refining Co., comprised three sections each of 500-ton daily rated capacity—a copper section, an oxide lead section, and a zinc-lead section. The zinc-lead section or oxide lead section was also used at times to treat zinc-copper ore. The zinc-copper ore supply came from California mines. The feed to the copper section came almost exclusively from the National Tunnel & Mines Co. operation; the feed to the oxide lead section came from the Tintic Standard mine; and the feed to the zinc-lead section came principally from the Park Utah Consolidated property at Park City.

Two copper smelters—the Garfield plant of the American Smelting & Refining Co. and the Tooele smelter of the International Smelting & Refining Co.—were active throughout 1944, except for brief periods of shut-down caused by labor difficulties. The combined rated capacity of these plants remained at about 1,900,000 tons of charge a year. The Garfield smelter received almost the entire output of the Utah Copper Co., which represented by far the largest part of its charge. In 1944 the sulfuric acid plant, operated in conjunction with the Garfield smelter, was enlarged to meet a greater demand for acid

petroleum refineries and fertilizer plants. The Tooele copper plant treated concentrates and ores principally from the National Fuel & Mines Co. operation.

Three lead smelters—the Midvale smelter operated by the United States Smelting, Refining & Mining Co., the Tooele smelter operated by the International Smelting & Refining Co., and the Murray smelter operated by the American Smelting & Refining Co.—were active throughout 1944. The combined rated operating capacity of these three plants was about 70,000 tons of charge per year. The Murray plant treated lead concentrates, lead ores, and siliceous ores mostly from mines in Idaho and Utah. The Midvale plant treated lead concentrates, lead ores, and siliceous ores mostly from its company-owned properties in Utah. The Tooele plant, operated in conjunction with the Tooele slag-fuming plant, treated zinc-lead ore and zinc-copper ore, lead concentrates and zinc concentrates, and residues from company-owned operations as well as custom sources; the combinations of these two plants were the most versatile metallurgical operation in the Salt Lake Valley area and continued to offer a market for ores that otherwise might have been unsalable.

Net production of metals in Utah in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

¹ No placers operated in 1944.
² Tintic district lies in both Juab and Utah Counties.
³ Property not counted as a "mine"; material crushed for use in cement.

BEAVER COUNTY

Pine Grove district.—The only output from the Pine Grove district in 1944 was zinc-lead ore from the Wah Wah mine shipped to the Midvale (Utah) flotation concentrator.

Bucky district.—The Prosper Mining Co. operated its Old Hickory mine in 1944 from March through November and shipped 422 tons of siliceous copper ore to the Garfield smelter.

San Francisco district.—A total of 3,222 tons of material from the Horn Silver mine dump was shipped direct to smelters in 1944; the material comprised 3,075 tons of siliceous gold-silver ore and 147 tons of lead ore. Considerable work was done during the year in timbering the King David shaft and connecting this shaft with the adjoining Horn Silver mine workings. Production from the Horn Silver mine, operated through the King David shaft, is anticipated during 1945. Other production in the district during 1944 was mostly waste copper ore shipped direct to smelters from the Imperial group and Cactus properties.

Star and North Star district.—James D. Williams, lessee of the Harrington-Hickory mine, operated the property throughout 1944. The output comprised 380 tons of silver ore, 595 tons of lead ore, and 56 tons of zinc-lead ore, all of which was shipped to smelters; in addition, 87 tons of zinc-lead ore were shipped to the Midvale concentrator for milling. Most of the ore shipped was oxidized. Lessees operated the Moscow Silver Mines Co. property and shipped 820 tons of silver ore to the Garfield smelter and 929 tons of rich zinc ore to the Bauer mill.

BOX ELDER COUNTY

Crater Island district.—Some copper ore was shipped direct to the Garfield smelter from the Copper Blossom property.

Lucin district.—A lessee shipped copper ore (125 tons), silver ore (40 tons), and lead ore (35 tons) direct to smelters from the Copper Mountain property.

Promontory district.—The Lakeview Mining Co. shipped oxidized zinc-lead ore from the Lake View Carbonate mine to the Tooele lead smelter.

IRON COUNTY

Indian Peak district.—The only output from Iron County in 1944 came from the New Arrowhead Mining Co. which operated its Arrowhead property throughout the year. The production consisted of 759 tons of oxidized zinc-lead ore which was shipped to the Tooele lead smelter.

JUAB COUNTY

Detroit district.—The Detroit district lies in both Juab and Millard Counties, but in 1944 all the production came from the Juab County section and was gold-silver ore from the Copperhead mine shipped to the Garfield smelter.

Fish Springs district.—Lessees shipped some lead ore to the Murray smelter from the Utah Mines group.

Tintic district.—The Tintic district, which lies in both Juab and Utah Counties, is reviewed here. The table that follows gives the metal production in each section of the district in 1944, a comparison with the total in 1943, and the grand total from 1869 to 1944.

Mine production of gold, silver, copper, lead, and zinc in Tintic district, Juab and Utah Counties, Utah, 1943-44, and total, 1869-1944, in terms of recovered metals

	Mines pro- ducing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value

¹ Figures not available.

During 1944, as in previous years, the Tintic district was the principal source in the State of highly siliceous ores that are used both as reverberatory and converter flux at the copper smelters in the Salt Lake Valley. However, in 1944 the output of such material was substantially less than in former years and much was dump material. The emphasis was on base-metal ores, particularly zinc-lead ores, and the zinc output of the district was greater than in any other year.

The Chief Consolidated Mining Co. operated its Chief No. 1 property in Juab County throughout the year; and the company Gemini, Eureka Hill, and Plutus mines were idle. Almost all the output from the Chief No. 1 mine was zinc-lead ore and was extracted from the 1,800- to the 2,250-foot level; in addition, a small quantity of siliceous silver ore and lead ore was shipped to the Garfield smelter.

The output of zinc-lead ore from the Chief No. 1 mine was nearly double that in 1943, and all was shipped to the Bauer custom mill of the Combined Metals Reduction Co. for treatment. According to the company report, the production in 1944 comprised 80,154 tons of zinc-lead ore and 360 tons of siliceous ore, a total of 80,514 tons of ore containing 1,322 ounces of gold, 291,479 ounces of silver, 77,303 pounds of copper, 5,076,239 pounds of lead, and 10,232,763 pounds of zinc.

According to the company printed annual report for the year ended December 31, 1944, pumping operations have resulted in lowering the water in the Chief No. 1 until now the company is mining below the 2,250-foot level and has sufficient control of the mine water to proceed at depth. The control of the water in the Chief No. 1 mine has been a problem of major proportions, and the work incident to its solution was concluded in 1944.

Because of the extreme labor shortage the development program of the Chief Consolidated Mining Co. was limited by necessity to its Chief No. 1 mine. In 1944 a total of 7,365 feet of development—5,222 feet of drifts, 1,880 feet of raises, and 263 feet of winzes—was completed. The company printed annual report states further that every effort has been extended toward mining the zinc-lead ore bodies below the water level, hence the development program on areas within the company property of 10,000 acres has had to be postponed until the present deficiency in the strategic metal situation has been relieved. However, when this occurs the company intends to resume development in the upper levels of the Chief No. 1, Apex Standard, Eureka Hill, and Gemini mines.

The Mammoth Mining Co. was the second most important producer in the Juab County section of the Tintic district in 1944; the company shipped about 17,000 tons of siliceous gold-silver ore to the Garfield smelter. Philip P. Clark operated the Godiva mine under lease throughout the year and shipped 3,017 tons of high-grade siliceous silver ore to Garfield. Lessees operated the Dragon & Martha Washington and the Empire groups, both owned or controlled by the International Smelting & Refining Co., and 458 tons of siliceous ores were shipped to smelters from these properties. None of the properties owned or controlled by the United States Smelting, Refining & Mining Co. were active in 1944. Other production in the Juab County section of the Tintic district included zinc-lead milling ore from the Showers group and Alaska mine and ore of several classes from the Showers group and the Windridge and Esther mines, all of which was shipped to smelters.

The major part of the recoverable metal output of the Utah County section of the Tintic district in 1944 was contained in ores produced by the Tintic Standard Mining Co. and its subsidiary companies. The following operating details were taken in part from the company printed annual report for the year ended December 31, 1944. Ore produced by the Tintic Standard mines (including the Iron Blossom) was 28,145 tons, 29,560 tons less than in 1943.

Operations during 1944 were limited by such a serious shortage of underground men, particularly those directly engaged in production, that output was below that necessary for profitable production. The shortage of mine labor prevailed throughout the State, but operations of the Tintic Standard Mining Co. were acutely affected by the increased employment available in new industrial plants and at surface jobs for men living in the towns and districts from which most of the company crews are obtained.

The shortage of labor, in addition to curtailing production substantially, made it necessary to suspend important development. Drifting on the 1,570-foot level and in the Tintic Standard-North Lily Development Unit was suspended. Because no improvement in the labor situation was anticipated in the near future, near the end of 1944 certain sections of the Tintic Standard mine were allotted to leasers, and production improved. This type of operation is expected to be extended in 1945. The Eureka Lilly mines were again operated only by lessees; production amounted to 7,371 tons of siliceous gold-silver ore, which was shipped direct to the Garfield smelter. The Colorado Consolidated Mines Co. property was operated also on lessee account, and production amounted to 6,982 tons of siliceous gold-silver ore shipped to Garfield. All operations were carried on in areas of the mine adjacent to the No. 4 and No. 1 shafts. The improvement and rehabilitation program started in 1943 was completed in 1944, with the result that output from this mine was increased greatly.

Development of the area owned by the Eureka Lilly Consolidated Mining Co. and the Twentieth Century Mining Co. was suspended during the latter part of 1944 by the Tintic Standard Mining Co. and the North Lily Mining Co., owing to shortage of labor. The Development Unit is the result of, and in accordance with, a joint development program undertaken by the Tintic Standard Mining Co. and the North Lily Mining Co. Production in 1944, before development was suspended, totaled 677 tons of copper ore from the Twentieth Century

mine shipped to the Garfield smelter. Development in 1944 totaled 836 feet of drifts, 101 feet of raises, 7 feet of shafts, 1,049 feet of diamond drilling, and 20 feet of long-hole drilling. Development in all other properties of the Tintic Standard Mining Co., exclusive of development at the Cougar (fluorspar) mine, comprised completion of 3,562 feet of drifts, 614 feet of raises, 68 feet of shafts, 575 feet of diamond drilling, and 2,745 feet of long-hole drilling.

An aggregate of 43,175 tons of ore of all classes was mined in 1944 by the Tintic Standard Mining Co. and its subsidiary companies and lessees, including the Development Unit. This output compared with a total of 73,296 tons mined in 1943 from the same sources. The total metal content in 1944 was 2,587 ounces of gold, 399,568 ounces of silver, 459,141 pounds of copper, and 5,183,255 pounds of lead. Over 4,000 tons of lead ore from the Tintic Standard mine were milled at the Tooele concentrator, making a lead concentrate and a siliceous tailing. The purpose served by milling this lead ore was to eliminate much of the silica from the lead blast-furnace charge.

The American Smelting & Refining Co. continued to ship siliceous gold-silver ore from the Harold dump to copper smelters in the Salt Lake Valley area; 56,587 tons of such material were shipped in 1944 to copper smelters at Garfield and Tooele compared with 71,779 tons in 1943. The material contained about 3 percent lead, in addition to the gold and silver. The Tintic Standard Mining Co. received a flat price per ton for material sold from the dump.

During 1944 the North Lily Mining Co., on its own account, conducted as active a program of mining and development as the shortage of manpower would permit, operating the North Lily mine, Tintic Bullion lease, and Eureka Bullion lease. The most productive property was the Tintic Bullion lease, from which the output was 6,344 tons of rich gold ore and 425 tons of zinc-lead ore, all shipped to various reduction plants of the International Smelting & Refining Co. at Tooele. It was followed by the Eureka Bullion lease, which yielded 4,820 tons of gold-silver ore shipped to the Tooele copper smelter. The output from the North Lily mine was 697 tons of gold-silver ore shipped to the Tooele copper smelter. The total development completed by the North Lily Mining Co. in 1944 comprised 4,845 linear feet of drifts, crosscuts, and raises and 4,453 feet of diamond drilling. Other production in the Tintic district, Utah County section, in 1944 included gold-silver ore from the May Day mine, Utah Con group, and Homansville Mill tailings dump and silver ore from the Zuma mine, all shipped to smelters.

MILLARD COUNTY

Notch Peak district.—The Kanosh Leasing Co. operated the "M & M" mine for about 3 months—September through November 1944. During the period of operation 112 tons of oxidized zinc ore assaying over 25 percent zinc were shipped to the Tooele slag-fuming plant; the ore was fumed at Tooele without previous smelting in the lead blast furnace. Production at the mine was limited by fuming-plant requirements.

PIUTE COUNTY

Mount Baldy district.—Gold ore (82 tons) and lead ore (99 tons) from the Deer Trail mine, shipped to a smelter by Sierra Nevada Ltd., and gold-silver ore (86 tons) from the Deer Trail dump, shipped to a

smelter by a lessee, comprised the output from the Mount Baldy district in 1944.

Ohio district.—The bulk of the output from the Ohio district was zinc-lead ore from the Cascade mine, shipped to the Midvale concentrator in 1944 by Floyd Moore. The property was operated from May 1 to November 1. Other production in the district was gold ore from the Shamrock mine and lead ore from the Bully Boy mine, all shipped to smelters.

SALT LAKE COUNTY

Big and Little Cottonwood districts.—Zinc-lead ore shipped to smelters from the Cardiff mine and lead ore from the Tanner's Flat mine comprised the output from the Big Cottonwood district in 1944.

Alta United Mines Co. operated its South Hecla property in the Little Cottonwood district throughout the year. Development was confined to the Dwyer drain and transportation tunnel of the South Hecla mine, but operations were limited because of lack of miners; however, considerable repair and rehabilitation work was done to surface structures and in the timbered areas of the mine. Test shipments of ore were made from four separate places in the mine and totaled 202 tons of ore containing 21 ounces of gold, 7,642 ounces of silver, 9,915 pounds of copper, 5,549 pounds of lead, 3,866 pounds of antimony, and 7,591 pounds of bismuth; the ore also contained some tungsten which was not saved.

The Bureau of Mines did considerable development in the district during 1944, most of which was confined to the properties of the Alta United Mines Co. Other production in the district came from the Columbus mine.

Smelter district.—All the output credited to the Smelter district in 1944 was material shipped to smelters from slag dumps, various assay office clean-ups, and railroad yards.

West Mountain (Bingham) district.—The Bingham district, by far the most important mining area in Utah, produced 91 percent of the gold, 62 percent of the silver, virtually all of the copper, 59 percent of the lead, and 49 percent of the zinc output of the State in 1944. The total value of the metal output declined 10 percent from 1943 but again surpassed that of any other district in the United States by a wide margin. The value of the total production in the district from 1865 to 1944 is exceeded only by the all-time production of the Butte district in Montana. The following table shows production from mines in the Bingham district in 1943 and 1944 and the total from 1865 to 1944.

Mine production of gold, silver, copper, lead, and zinc in Bingham or West Mountain district, Salt Lake County, Utah, 1943-44, and total, 1865-1944, in terms of recovered metals

Year	Mines producing	Ore (short tons)	Gold (lode and placer) (fine ounces)	Silver (lode and placer) (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value
1943.....	14	36,532,301	343,551	5,404,365	644,495,100	70,873,600	46,809,500	\$110,022,698

Total, 1865-1944..		(1)	5,454,229	137,466,112	² 4,333,954	² 1,526,963	² 457,434	1,675,965,677

¹ Figures not available.

² Short tons.

Because of circumstances beyond its control, the Utah Copper Co. in 1944 did not equal its record rate of production established in 1943; however, the company remained the leading world producer of copper. The company produced virtually all the State output of copper and as a byproduct made an important contribution to Utah's gold and silver output. An acute shortage of skilled and unskilled labor, which became more severe as the year progressed, prevented continuation of maximum production from the open-pit operations of the company at Bingham. Every effort was made to obtain Mexican workmen for surface employment at the company's Utah property, but without success. A few Puerto Rican workmen, however, were employed with some success at the open-pit operations. In 1944 ore and waste were mined at the rate of approximately 170,000 tons a day compared with 218,000 tons in 1943. The practice of piling the waste rock in gulches adjacent to the pit was continued. Ore was milled at the Arthur and Magna plants at the rate of about 80,000 tons a day compared with 97,000 tons in 1943; the plants were shut down 4 days during the year because of a failure of the tailings dike. The average grade of the ore treated was about the same as that in 1943. Average mill recoveries in 1944 were slightly higher than in 1943. The new power plant, in process of construction during 1943, was completed in February 1944.

The printed annual report of the Kennecott Copper Corp. for the year ended December 31, 1944, says that the most important event at the Utah unit was the starting of power generation in February at the new Central power plant. The 50,000-kw. steam turbo-generator unit now installed has been furnishing all the power required for milling the reduced tonnages prevailing since May. The mine has continued to operate on purchased power. When conditions permit, it is understood that additional generating equipment sufficient to provide Utah's (unit) full requirements of power may be added.

Breaks in the dikes enclosing the tailings have twice been a source of stoppages in milling operations. The company report states that extensive work was done on the dikes enclosing the 6,000-acre tailings-impounding pond. For the past 3 years breaks in the dikes, which have now reached a considerable height, have been a source of trouble and in August 1944 caused a complete suspension of milling operations for 4 days. Two years ago an inner protecting dike, about 150 feet inside the pond, was constructed along the north side, and as no breaks have since occurred in the north side an inner dike appears to be the solution of these difficulties. This same system of inner reinforcements is now being provided on the east, south, and west sides of the pond; the work was more than half completed at the end of 1944.

In addition to the great quantity of copper contained in the copper concentrates made at Arthur and Magna, the company, by forced leaching of its waste dumps, produced copper precipitates in 1944 which contained about 36,000,000 pounds of copper, a gain of about 8,000,000 pounds compared with 1943. This was the largest yearly output of copper precipitates on record. The precipitating plant is at Lead Mine in the mouth of Bingham Canyon.

In December 1943 the company began driving an 18- by 24-foot transportation adit, 4,600 feet in length, which is large enough to accommodate a standard locomotive. The adit was started at the lower end of the town of Bingham and will end under the present floor of

the open pit. When 1944 closed, 3,900 feet of the proposed 4,600 had been driven, and concrete lining had been placed where heavy ground was encountered. After driving is completed, 3,800 feet of the tunnel will be lined with concrete, and it is expected that the work will be completed by the middle of 1945.

The Boston Consolidated mine, owned by the Utah Copper Co., was operated under lease all of 1944 by the American Smelting & Refining Co. The tonnage of copper ore mined and shipped to the Garfield smelter amounted to about half of that mined in 1943, and the grade of the ore mined was much lower than in 1943.

The chief source of zinc and lead production in the Bingham district continued to be the United States & Lark property operated by the United States Smelting, Refining & Mining Co. The district production of lead and zinc in 1944 declined about 8,500,000 pounds each, the direct result of a similar decline in output at the United States & Lark property. The company mined and shipped about 62,000 tons less zinc-lead ore to its Midvale concentrator than in 1943; the metal content of the ore was slightly higher in silver and copper content but about the same in gold, lead, and zinc. In addition to the zinc-lead milling ore, the company shipped a total of about 17,000 tons of gold ore, lead ore, and zinc-lead ore to smelters. The mine retained its position as the leading lead producer and second-largest zinc producer in the Western States, and it also produced substantial quantities of gold, silver, and copper. Development was about the same as in 1943 and involved the completion of 254 feet of shaft, 19,387 feet of raises and drifts, and 2,802 feet of diamond drilling. Other properties in the Bingham district owned or controlled by the United States Smelting, Refining & Mining Co. and active in 1944 included the Montana-Bingham Consolidated and Niagara. Production in 1944 from these two properties comprised 12,865 tons of zinc-lead milling ore treated at the Midvale concentrator and 1,438 tons of gold-silver ore shipped to a smelter. The company printed annual report for the year ended December 31, 1944, states that operations of the mines at Bingham and the flotation mill and smelter at Midvale were continuous throughout the year. Output was lower by reason of the growing manpower shortage; the grade of ores mined was about the same as in 1943. All the lead bullion produced at the smelter was treated at the electrolytic lead refinery at East Chicago, Ill.

The Apex-Delaware group of properties was operated continuously in 1944 by the National Tunnel & Mines Co. on both company and lease account. The properties are developed through the 5-mile Elton tunnel, the portal of which is a short distance from the reduction plants of the International Smelting & Refining Co. near Tooele, Utah. The following operational details are given by the company printed annual report for the year ended December 31, 1944: Shortage of manpower prevented capacity operations during 1944. This condition became steadily worse throughout the year, resulting in a decrease of almost 50 percent in number of employees at the end of the year. As a result, production of ore declined; however, output of copper, silver, and gold increased slightly because the grade of ore was better than in 1943. Production in 1944 comprised 152,370 tons of copper ore treated at the Tooele copper concentrator, 6,840 tons of zinc-lead ore treated at the Tooele zinc-lead concentrator, and 93 tons of zinc-lead ore shipped to the Tooele lead blast furnace.

During the year development, curtailed on account of the shortage of labor, amounted to the completion of 4,294 feet of crosscuts and raises and 5,169 feet of diamond drilling. A crosscut was driven on the 2,700-foot level from the Rood shaft to explore the Alphabetical lime beds. The "A" bed was reached and showed some mineralization but no commercial ore. Some diamond drilling was done below the 3,300 level in the Yampa lime.

The company enlarged its holdings in the Bingham district during the year by a merger with the Utah Metal & Tunnel Co., owner of adjoining mining property.

In 1944 the Ohio Copper Co. operated a 1,500-ton flotation plant at Lark (Utah) for the treatment of old tailings accumulated from former milling operations, a leaching plant for recovery of copper from old mine stopes in mining ground formerly owned by the company under a royalty agreement with the present owners, and a small underground electric railway which served the Ohio Copper Co. and an adjoining mine of the United States Smelting, Refining & Mining Co. Although 493,413 tons of material were treated, compared with 469,747 tons in 1943, the output of copper was smaller, owing to a decline in grade of material treated; that treated in 1944 contained about 7.7 pounds of gross copper per ton. The company also produced 295 tons of copper precipitates by leaching. At the beginning of operations at the Columbia group in 1937 the Ohio Copper Co. estimated that 5,000,000 tons of tailings were available for re-treatment. By the end of 1944 2,680,000 tons had been processed, theoretically leaving 2,320,000 tons still available for treatment. However, according to the company printed annual report for the year ended December 31, 1944, all of this total cannot be reclaimed. Owing to location, the remaining tonnage will present more difficult reclamation problems; in addition, the copper content of the material left is lower than of that treated in past years.

The Butterfield group, including the Queen property, was operated throughout 1944 by the Combined Metals Reduction Co. and lessees. A total of 25,905 tons of zinc-lead ore was shipped to the Bauer mill of the company, and 316 tons of ore of all classes were shipped to smelters. The output was somewhat less than in 1943.

Other production in the Bingham district included zinc-lead mill ore from the New England mine and crude ore of several classes from the Kaign and Bingham Congor properties, all shipped to smelters.

SAN JUAN COUNTY

La Sal district.—Late in 1943 the Ohio Copper Co. completed the construction and equipment of a leaching plant with a daily capacity of 250 tons at its Big Indian property 6 miles south of La Sal. The production of copper from the plant was under contract to the Metals Reserve Company, but early in 1944 the War Production Board diverted the supply of acid relied on and absolutely essential to the leaching method of operation. The Ohio Copper Co. states in its annual report for the year ended December 31, 1944, that it had a large investment in a property dependent on an acid-leach process, but no acid was available; consequently, it turned to concentration by flotation. Although the treatment of oxidized copper ore by flotation has never been particularly successful, the company after

laboratory tests adopted a new technique that had indicated a satisfactory recovery of the metal values. To determine further the feasibility of this type of operation, sufficient equipment was installed at the Big Indian plant to permit the treatment of 40 to 50 tons of copper ore daily by this new flotation process.

After 4 months of operation results warranted increasing the flotation capacity to 250 tons of ore a day. Sufficient equipment had been installed by the end of 1944 to permit operation at the rate of 175 tons a day; early in 1945 the full 250-ton capacity is expected to be reached. During 1944, 8,009 tons of copper ore containing 397,246 pounds of copper were treated, making 528 tons of copper concentrates which contained 275,848 pounds of copper, indicating a copper recovery of 69 percent.

SUMMIT AND WASATCH COUNTIES

PARK CITY REGION

The Park City region includes the Uintah district in Summit County and the Blue Ledge and Snake Creek districts in Wasatch County. Mines in the Park City region, severely handicapped by acute shortages of labor, produced a smaller quantity of all metals than in 1943. The region continued to supply large quantities of tailings to smelters to be used for flux and also reconcentrated for zinc and lead. The following table shows the production and total value of all metals in 1944 compared with 1943 and the total from 1870 to 1944.

Mine production of gold, silver, copper, lead, and zinc in Park City region, Summit and Wasatch Counties, Utah, 1943-44, and total, 1870-1944, in terms of recovered metals

Year	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)	Total value
1943	15	362,950	19,559	2,001,555	1,265,100	32,044,200	22,973,000	\$7,156,755
1944	8	203,001	15,149	1,429,650	956,800	23,319,600	19,111,000	5,720,245
Total, 1870-1944	(1)		531,028	232,731,448	67,004,113	2,373,867,431	653,188,611	357,077,148

¹ Figures not available.

The total tonnage of ore mined and treated by the Silver King Coalition Mines Co. in its 800-ton flotation mill was 54,252 tons compared with 95,800 tons in 1943, a decrease of 43 percent. Labor shortage and operational difficulties handicapped both mining and development to a considerable extent in 1944.

The Quota Committee of the Premium Price Plan for Copper, Lead, and Zinc adjusted the company quotas effective June 1, and although it was granted zero quota and a 5-cent premium for copper, zero quota and the A and B premium (2½ cents a pound for each premium) for lead, and zero quota and A, B, and C premium for zinc, the company ended the year 1944 with a net profit of \$6,870 after all costs and depreciation (\$24,414) had been deducted. The mine was operated 305 days, but the 800-ton concentrator worked only 104 days on a three-shift basis because of the low production of ore. The company printed annual report for the year ended December 31, 1944, says that mining and milling operations at the Park City property were carried

on continuously throughout 1944. Effective June 12, underground operations were converted from two shifts to one shift per day in order to place a larger portion of the available manpower on extraction and development. The labor shortage within this area has been aggravated since that date so that at the present time 65 additional men are required for efficient operations on one shift. The monthly average of man-shifts worked per day dropped from 372 to 246 from January to December. The 54,252 tons of zinc-lead ore milled made 5,189 tons of lead concentrates and 2,729 tons of zinc concentrates; the total metal content of the concentrates was 537 ounces of gold, 428,239 ounces of silver, 207,890 pounds of copper, 7,042,100 pounds of lead, and 3,418,499 pounds of zinc. The lead concentrates averaged 67.1 percent lead and were shipped to the Murray smelter, and the zinc concentrates averaged 61.8 percent zinc and were shipped to the Anaconda Copper Mining Co. zinc smelter at Anaconda. In addition, 236 tons of silver-lead ore containing 14 ounces of gold, 14,814 ounces of silver, 4,605 pounds of copper, and 218,756 pounds of lead were shipped to the Murray smelter.

Total development footage completed during the year included 11,802 feet of drifts, 1,496 feet of raises, and 246 feet of winzes. On September 28, development on the 1,960 level struck a large flow of water and the pumps on the 1,900 level were drowned; the workings of the West End and 5,141 Section of the mine were flooded. Pumps were installed, and by December 29 the water had been lowered to the 1,900 level. Additional pump stations have been cut on the 1,700 and 1,900 levels, and new pumps and pipe lines were being installed during the first part of 1945. Development on the 1,960 level opened up the continuation of one of the West End ore bodies. The small amount of development done after encountering the ore and before the inundation makes impossible any reliable estimate of the extent of this body. The ore where opened is high-grade silver-lead with low zinc.

In 1944 the Park Utah Consolidated Mining Co. operated its Park Utah Consolidated mines group in Summit County and its Park Utah Consolidated group in Wasatch County and produced 38,986 tons of ore, of which 32,146 tons came from Summit County and 6,840 tons from Wasatch County. The extensive unwatering and development program started in 1943 had reached its first objectives early in 1944. The new ore opened was of good grade and added much to the total metal output of the company. All the ore mined and shipped during 1944 went to the various reduction plants of the International Smelting & Refining Co. at Tooele and comprised 38,310 tons of zinc-lead mill ore, 460 tons of lead smelting ore, and 216 tons of zinc-lead smelting ore. The zinc-lead ore from this property is very amenable to flotation, and as a result the recoveries obtained are among the highest in the State. The 38,986 tons of ore mined and shipped contained 823 ounces of gold, 556,511 ounces of silver, 316,317 pounds of copper, 9,493,412 pounds of lead, and 9,628,150 pounds of zinc. This tonnage represents a decrease of more than 20 percent from 1943, but the average grade was higher.

The company printed annual report for the year ended December 31, 1944, says that the output of the company and the prosecution of development operations have been seriously handicapped by war conditions, of which the shortage in manpower was the primary factor. During the year the pay roll averaged 290 men, compared

with 344 in 1943 when a deficiency in labor already existed. In June 1944 the shortage became so acute that two-shift operation was replaced by single-shift. During the remainder of the year the labor supply deteriorated further. Development completed during the year consisted of 14,586 feet of drifting, raising, and crosscutting and 4,325 feet of diamond drilling.

The New Park Mining Co. mined and shipped to the Midvale concentrator 57,640 tons of zinc-lead ore in 1944 compared with 55,811 tons in 1943. The decline in tonnage was attributed to the prevailing shortage of manpower. The company was the leading producer of gold, copper, and lead in the Park City region. The gold-silver-copper-lead-zinc ore mined in 1944 contained 15,186 ounces of gold, 449,930 ounces of silver, 719,317 pounds of copper, 8,005,803 pounds of lead, and 10,732,276 pounds of zinc and when compared with the ore mined in 1943 indicates a decline in gold, silver, and copper content but an increase in lead and zinc content. Development completed in 1944 comprised 2,870 feet of crosscuts and drifts, 1,118 feet of raises, 147 feet of shaft, and 4,162 feet of diamond drilling; the company also completed 478 feet of development in the Star of Utah tunnel.

The company in its printed annual report for the year ended December 31, 1944, states with regard to development for the year: In order to keep the right ratio of development work to extraction of ore it is necessary to keep reserves blocked out far enough ahead of production to permit efficient planning and operating. The shortage of labor has thrown this ratio out of balance and to correct this the company has contracted for a program of diamond drilling. The results have been successful in locating two new ore bodies. The first is a 10-foot fissure 460 feet north of the main ore body, known as the Pearl fissure; the company is now crosscutting to open it up from the 1,020 level. The second is in the Mayflower-Galena fissure over 1,000 feet west of the main ore body; this fissure is wide and the ore, although rather low-grade where cut, is improving with development. These two ore bodies should add considerably to the company ore reserves. Work was resumed in the Star tunnel, where the company intends to follow the ore opened near the Mariam claims to the projected junction with the large fissure on those claims, which is believed to be the westward extension of the Mayflower-Galena fissure. The company is sinking the main shaft to open up additional levels to keep development well ahead of extraction of ore.

A small flotation mill on Silver Creek just below the Silver King Coalition Mines Co. 800-ton flotation mill is used by Rueben Garbett to re-treat the current tailings from the Silver King Coalition mill. In 1944 about 46,000 tons of such tailings were treated, producing 552 tons of zinc middlings which were shipped to the Midvale concentrator for further treatment.

A total of 5,011 tons of old tailings from various claims on Silver Creek were shipped to smelters and concentrating mills, principally the Garfield smelter. The tailings contained a small quantity of lead, zinc, and silver and were shipped only because of Quota Committee premiums. These tailings were one source of siliceous material available with a very small expenditure of manpower. Usually they are used at copper smelters as reverberatory flux.

Other production in the Park City region included zinc-lead and silver ore from the Park Flag mine (formerly American Flag) and zinc-lead ore from the New Quincy mine.

TOOELE COUNTY

Tooele County continued in 1944 to rank fourth among the metal-producing areas in Utah. Mines in the county produced gold, silver, copper, lead, and zinc valued at \$2,542,218 compared with \$3,243,258 in 1943.

Camp Floyd district.—Crude siliceous gold and gold-silver ore from the Geyser Marion group and Sacramento properties, shipped to the Garfield smelter, comprised the output from the Camp Floyd district in 1944. These properties were granted an exception to the gold-mine closing order so as to supply siliceous ore to copper smelters for fluxing. The Sacramento was operated under lease by Charles Mercer, and the Geyser Marion group was operated until November 7 by the Geyser Marion Co. and thereafter by A. J. Kirkman under lease agreement.

Clifton district.—The Gold Hill arsenic mine was operated under lease in 1944 by the United States Smelting, Refining & Mining Co. The principal output was arsenic ore from which some gold-silver ore was derived as a byproduct. The property was closed in January 1945, after the known ore bodies were exhausted.

Dugway district.—The Rip Van Winkle Consolidated Mining Co. began operation of its Smelter Canyon mine September 13 and continued the rest of the year. Production included 593 tons of zinc-lead ore and 50 tons of silver ore shipped to the Tooele smelter and 305 tons of zinc-lead milling ore shipped to the International sulfide concentrator and Combined Metals mill at Bauer. A small lot of gold ore was shipped to a smelter from the Final Success mine.

Lakeside district.—The Monarch mine was operated by the Lakeside Monarch Mining Co. for 6 months in 1944 and produced 680 tons of lead ore shipped to the smelter at Murray.

North Tintic district.—The output from the North Tintic district in 1944 consisted of 30 tons of zinc ore from the dump of the Scranton mine and was shipped to the Tooele slag-fuming plant.

Ophir district.—The Hidden Treasure mine, operated by the United States Smelting, Refining & Mining Co. from January 1 to May 31, 1944, was the chief producer in the Ophir district during the year; output was 1,458 tons of ore of several classes shipped to smelters and 133 tons of zinc-lead-copper mill ore shipped to the Midvale concentrator. The Ophir Development Co. operated its Ophir Hill property throughout 1944 and produced 772 tons of ore (all classes) which was shipped to smelters and 401 tons of zinc-lead ore which was shipped to the Tooele sulfide concentrator; the company also produced 400 tons of ore of several classes from the Montana Lease, an adjoining property. Other producers in the district included the Kearsarge group of properties, Shoo Fly group, Togo claim, and Wandering Jew mine.

Rush Valley district.—The West Calumet (Calumet) mine operated by the Combined Metals Reduction Co. was one of the principal producers of zinc and lead in the State during 1944 and was operated on both company and lessee account. Production consisted of 40,311

tons of zinc-lead ore which was treated at the Bauer mill and 147 tons of lead ore which was shipped to the Tooele lead smelter. A greater output could not be attained at this property during 1944 because of the prevailing labor shortage. Other production in the district included ore of several classes shipped to smelters from the Honerine-Galena King group by the Combined Metals Reduction Co., the Bluestone group, Ben Harrison mine, and the Blue Eagle mine. Milling ore from the Honerine-Galena King (zinc-lead) and Bluestone (lead) properties was shipped to the Bauer mill and Tooele sulfide concentrator, respectively.

Smelter district.—Again in 1944, the second-largest source of zinc in Utah was zinc slag fumed at the International Smelting & Refining Co. plant at Tooele. The plant was operated continuously throughout the year and fumed a total of 133,378 tons of hot slag, cold slag, and crude ore. The production from the operation was a zinc-lead fume which was treated further to separate the zinc fume from the lead fume. The zinc fume averaged 72.3 percent zinc and was shipped to the International Minerals & Metals Corp., Bartlesville, Okla.; the lead fume averaged 42.8 percent lead and was re-treated at the Tooele lead blast furnace. Although the plant treated 133,378 tons of material, only the metals recovered from the fuming of 48,880 tons of old zinc slag are credited to the slag-fuming plant as a prime producer and to the "Smelter district." The remainder comprised metals obtained from current slag derived from the smelting of ores and concentrates from mines in Utah and other States and from ore fumed directly, and these metals are credited to those mines. The recovery of zinc at the slag-fuming plant was higher than in 1943. The recovery of lead from ores treated in the lead blast-furnace-slag-fuming-plant circuit is exceptionally high, and ultimate loss of lead in the discarded slag in the fuming plant is very small.

Willow Springs district.—The Oro Del Rey mine was operated in 1944 on lessee account; 354 tons of lead ore containing considerable gold were shipped to smelters.

UTAH COUNTY

American Fork district.—The output from mines in the American Fork district in 1944 was zinc-lead ore shipped to various concentrating plants in the Salt Lake Valley. The Golden West Consolidated Mining & Leasing Co. operated its Dutchman group from January 1 through November 24 and shipped 676 tons of ore to the Bauer concentrator and Midvale concentrator. The Howell Mining Co. operated its Globe mine from April 15 to December 31 and shipped 340 tons of ore to the Tooele sulfide concentrator.

Tintic district.—Mines in the Utah County section of the Tintic district are reviewed under Juab County.

WASHINGTON COUNTY

Tutsagubet district.—James J. Smith and Emerald L. Coz began operating the Dixie mine in the Tutsagubet district on June 23 and continued to the end of the year. Production amounted to 596 tons of oxidized copper ore, which was shipped to the Garfield smelter.

GOLD, SILVER, COPPER, LEAD, AND ZINC IN WASHINGTON

(MINE REPORT)

By G. E. WOODWARD AND PAUL LUFF

SUMMARY OUTLINE

	Page		Page
Summary.....	462	Metallurgic industry.....	467

Ore classification.....	467	Metalline district.....	472

SUMMARY

Mines in Washington yielded gold, silver, copper, lead, and zinc valued, in terms of recoverable metals, at \$7,195,136 in 1944 compared with \$7,838,012 in 1943. The average prices paid for copper, lead, and zinc were higher than in 1943, which tended to maintain total value of metal output near the 1943 level despite a decline in output of each metal except lead; however, the total value was the lowest since the United States entered the present war. The output of lead exceeded that in any other year. The decrease in gold and silver resulted from a decline in production from the two leading gold and silver producers in the State—the Howe Sound Co., operating the Holden property in Chelan County, and Knob Hill Mines, Inc., operating its gold property in Ferry County. The Holden property was again the principal source of copper, and although the company treated a larger tonnage of ore in 1944 than in 1943 the gold, silver, copper, lead, and zinc content was less. The decreased production of zinc and the increased production of lead in Washington were the net result of treating a smaller tonnage of zinc-lead ore from the mines in Pend Oreille County having about the same zinc but a higher lead content than in 1943. The Pend Oreille Mines & Metals Co. was the principal zinc producer in the State, and the American Zinc, Lead & Smelting Co. was the largest lead producer.

Shortages of labor continued to be the chief deterrent to a greater output of base metals throughout the State. In 1942 and again in 1943 the Army furloughed soldiers for service in the mines, but no such help was forthcoming during 1944. Development to increase the current output of metals and develop new ore bodies was greatly curtailed. The Holden mine, largest metal mine in the State, closed the year with 38 percent fewer men working underground than at the beginning of the year. On July 1, 1944, the War Production Board and War Manpower Commission jointly sponsored a system whereby mines producing critical metals would receive a labor priority. The priority gave the mines a preference in the labor market both locally

and nationally; some help, although inadequate, was obtained from the use of this system. The premium price plan, inaugurated in 1942, was continued throughout 1944.

The Geological Survey and Bureau of Mines remained active during 1944 in aiding producers of critical metals from several properties in Washington. The diamond drilling of large mineralized areas in the Metaline district of Pend Oreille County by the Bureau of Mines was continued, with the result that the probable reserves of zinc-lead ore were increased substantially.

The Department of Agriculture, operating through the Forest Service, continued to administer the access-road program.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ³	Zinc ³
	<i>Per fine ounce</i>	<i>Per fine ounce</i>	<i>Per pound</i>	<i>Per pound</i>	<i>Per pound</i>
1940	\$35.00	\$0.711+	\$0.113	\$0.050	\$0.093
1941	35.00	.711+	.118	.057	.075
1942	35.00	.711+	.121	.067	.093
1943	35.00	.711+	.130	.075	.108
1944	35.00	.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price reflects bonus payments by Metals Reserve Co. for overquota production.

* \$0.71111111.

Mine production of gold, silver, copper, lead, and zinc in Washington, 1940-44, and total, 1860-1944, in terms of recovered metals

Year	Mines producing		Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)	
	Lode	Placer		Fine ounces	Value	Fine ounces	Value
1940	83	88	1,166,798	82,136	\$2,874,760	365,175	\$259,680
1941	61	56	1,238,509	84,176	2,946,160	402,030	285,888

Gold.—The output of recoverable gold from lode and placer operations in Washington in 1944 was 47,277 fine ounces, a 28-percent decrease from 1943. Only two mines producing gold in substantial quantities from siliceous ores remained active in 1944; all others were closed. The decrease in output of gold in the State was the result of marked declines in output at its two largest gold producers, namely, the Howe Sound Co. and Knob Hill Mines, Inc. The greater decrease was noted at the Holden property of the Howe Sound Co., where a larger tonnage of ore was mined and treated than in 1943 but of a much lower gold content; most of the ore was mined from ore bodies low in gold content while the new extraction shaft below the main haulage tunnel was being completed. Although Knob Hill Mines, Inc., treated ore with a slightly higher gold content, the tonnage treated in 1944 was sufficiently smaller than that treated in 1943 to show a net decrease in gold output. Ores of the Holden mine, valued also for their copper and zinc content, continued to be the chief source of gold in the State and in 1944 yielded 55 percent of the State total; it was followed by Knob Hill Mines, Inc., which treated gold ore throughout the year from its Knob Hill mine by cyanidation and concentration. These two properties, long producing most of the State output of gold, contributed over 94 percent of the total in 1944. Among other gold-producing properties were the Aurum mine in the Republic district of Ferry County and the Blue Ridge property of the Sierra Zinc Co. in the Northport district of Stevens County.

The total output of siliceous ore was 62,063 tons, principally gold ore, compared with 61,220 tons, virtually all gold ore, in 1943; it was treated as follows: 42,245 tons by combination cyanidation and concentration, 200 tons by straight concentration, and 19,618 tons shipped crude to smelters. Placers yielded 59 ounces of gold.

Silver.—The output of recoverable silver in Washington was 321,608 fine ounces in 1944, compared with 370,440 ounces in 1943; all the silver recovered was a byproduct of gold or base metals. Losses in output from mines in Benton, Chelan, Ferry, Snohomish, and Whatcom Counties more than offset gains from mines in Okanogan, Pend Oreille, and Stevens Counties. Virtually the entire State output of silver came from mines in Chelan, Ferry, Okanogan, Pend Oreille, and Stevens Counties. Mines in Chelan and Ferry Counties, for years the chief source of silver, yielded 73 percent of the State total in 1944. Gold ore yielded 40 percent of the total State silver; zinc-copper ore, 32 percent; zinc-lead and zinc ores, 26 percent; and gold-silver, silver, copper, and lead ores and placers, the remainder. The Knob Hill mine

of Knob Hill Mines, Inc., in Ferry County was again the largest silver producer in the State; it was followed by the Holden property of the Howe Sound Co. in Chelan County, the Kaaba property of the Kaaba-Texas Mining Co. in Okanogan County, and the Aurum group of properties in Ferry County; these four properties contributed 88 percent of the State total silver. Placers yielded 7 ounces of silver.

Copper.—The output of recoverable copper in Washington in 1944 was 12,338,000 pounds, or 16 percent less than in 1943. As in former years, virtually the entire State output of copper was recovered from the zinc-copper ores of the Holden property of the Howe Sound Co. The company shipped copper concentrates rich in gold to the Tacoma smelter and zinc concentrates to the Sullivan electrolytic smelter in Idaho for treatment. The copper concentrates contained nearly all the recoverable gold in the zinc-copper ore. The value of the gold content of the copper concentrates was equivalent to 55 percent of the value of the copper. Following the Howe Sound Co. as copper producers were the Kaaba mine of the Kaaba-Texas Mining Co. in Okanogan County and the Blue Ridge property of the Sierra Zinc Co. in Stevens County.

Lead and zinc.—The production of recoverable zinc in Washington in 1944 declined 598,000 pounds (2 percent) compared with 1943, but the output of recoverable lead exceeded that in any year of the State's history.

Mines in Pend Oreille County produced considerably more lead than in 1943 but a slightly smaller quantity of zinc. Shortages of manpower were again the greatest obstacle to maximum production. The gain in lead output was due principally to a pronounced change in lead content of the zinc-lead ores treated by the American Zinc, Lead & Smelting Co. from the Metaline Mining & Leasing Co. property; the decrease in zinc was due directly to a smaller output from the Pend Oreille Mines & Metals Co., which treated less zinc-lead ore than in 1943, but of about the same grade. Zinc-lead ore treated in 1944 in two flotation mills (Pend Oreille and Grandview) totaled 305,516 tons, compared with 311,245 tons in 1943. The ore averaged 2.08 percent in lead and 3.88 percent in zinc, compared with 1.70 and 3.80 percent, respectively, in 1943.

The Sierra Zinc Co. operated its Blue Ridge property in Stevens County until September 1, 1944, and was the fourth-largest producer of zinc in the State. The Howe Sound Co. recovered zinc from its zinc-copper ore and ranked fifth as a source of zinc; the output declined 44 percent from 1943. Most of the remaining lead and zinc produced was recovered from mines in Okanogan and Stevens Counties. Zinc and zinc-lead ore treated from mines in Stevens County amounted to 32,559 tons, compared with 21,112 tons in 1943, and zinc-lead ore treated in Okanogan County totaled 23,930 tons compared with 14,431 in 1943. The zinc content of ore treated from mines in Stevens County was the highest in the State.

¹ A floating washing plant supplied with gravel by a dragline excavator is called a "dragline dredge"; a stationary or movable washing plant supplied with gravel by any type of power excavator is called a "dry-land dredge."

MINING INDUSTRY

Seven properties in Washington produced 1,149,693 tons of ore in 1944—97 percent of the State total. This output included zinc-copper ore (64 percent) from the Holden mine in Chelan County; zinc-lead ore from the Pend Oreille, Metaline, and Grandview mines in Pend Oreille County and the Kaaba-Texas property in Okanogan County; zinc ore from the Blue Ridge property in Stevens County; and gold ore from the Knob Hill property in Ferry County.

Development completed on company account in these seven properties in 1944 included 21,464 feet of drifts, raises, and shafts and 41,766 feet of diamond drilling. Although the total footage of development work in 1944 exceeded that in 1943, it was confined mostly to current drifts preparatory to stoping and not to exploration necessary to open higher-grade ore. Aside from development and exploration on company account, the Government, through its agencies particularly the Bureau of Mines, completed several thousand feet of diamond drilling, mostly in the Metaline district of Pend Oreille County.

ORE CLASSIFICATION

Details of ore classification are given in the chapter of this volume on Gold and Silver.

Ore sold or treated in Washington in 1944, with content in terms of recovered metals

Source	Mines producing	Ore (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)
Dry and siliceous gold ore	5	59,165	20,434	128,471	-----	-----	-----
Dry and siliceous gold-silver ore	1	2,698	200	4,068	-----	-----	-----
Dry and siliceous silver ore	2	200	2	1,826	413	3,673	-----

Total, lode mines	25	1,180,662	47,218	321,601	12,338,000	11,650,000	23,808,000
Total, placers	3	-----	59	7	-----	-----	-----
	28	1,180,662	47,277	321,608	12,338,000	11,650,000	23,808,000
Total, 1944	26	1,131,281	65,244	370,440	14,630,000	10,044,000	24,406,000

METALLURGIC INDUSTRY

Lode mines in Washington produced 1,180,662 tons of ore in 1944, treated as follows: 42,245 tons in a cyanidation-concentration mill, 1,118,318 tons in straight concentration mills, and 20,099 tons shipped crude to smelters.

Cyanidation mills.—The only cyanide mill active in 1944 was, as in 1943, the 400-ton cyanidation-concentration mill of Knob Hill Mines, Inc. It cyanided a total of 38,741 tons of current tailings, from the flotation concentration of 42,245 tons of gold ore, and consumed 69,000 pounds of calcium cyanide, 483,000 pounds of lime, and 9,700 pounds of zinc dust; the operation was continuous throughout 1944.

Concentration mills.—Eight concentration mills in the State treated a total of 1,118,259 tons of ore, as follows: One plant 756,081 tons of zinc-copper ore, four plants 330,097 tons of zinc-lead ore, one plant 31,849 tons of zinc ore, and two plants a total of 232 tons of silver ore and lead ore; in addition, 59 tons of zinc ore were shipped to the Combined Metals Reduction Co. plant at Bauer, Utah, for treatment. The total rated capacity of the eight concentrating mills was 3,600 tons a day, but the average treated was slightly over 3,000 tons.

Mine production of metals in Washington in 1944, by methods of recovery, in terms of recovered metals

Method of recovery	Material treated (short tons)	Gold (fine ounces)	Silver (fine ounces)	Copper (pounds)	Lead (pounds)	Zinc (pounds)

BENTON COUNTY

The gold output from Benton County in 1944 came from a dry-land dredge that operated intermittently on Columbia River.

CHELAN COUNTY

Chelan Lake district.—In 1944 the Holden mine of the Howe Sound Co. was again the leading producer of gold and copper and second in silver in Washington, and it was fifth in zinc. The ore treated was 55,521 tons greater than in 1943 but was considerably lower in grade. The smaller gold and silver content contributed materially to the lowering of the State output of gold and silver, and the lower copper content was wholly responsible for the decrease in State copper output. In 1944 the company treated in its 2,000-ton concentrator 756,081 tons of ore, containing an average of 0.048 ounce of gold and 0.98 ounce of silver to the ton, 0.90 percent copper, and 0.37 percent zinc. The mill was operated three shifts a day, six and a half days a week, averaging 2,264 tons a day. The only equipment added to the milling plant in 1944 was a 36-inch jaw crusher, which was installed underground. The shortage of labor at the Holden property was particularly severe in 1944. The Howe Sound Co. states in its printed annual report, dated December 31, 1944, that at the Chelan property the underground force employed during December was 38 percent less than that available at the beginning of the year. The average number of men working in the mine was 25 percent less than during 1943; consequently, the amount of development and exploration that could be done was inadequate.

The new extraction shaft below the main haulage tunnel was not completed until late in the year, and, therefore, the production of ore of copper and gold content equal to that of former years was limited to ore obtained from development. Mining was largely confined to low-grade material occurring above the main haulage tunnel. Under agreement made with the War Production Board, premium payments were received for the copper produced from this source, and the concentrator was operated at greater than rated capacity throughout the year at some profit. Development completed during 1944 comprised sinking 190 feet of shaft, driving 16,091 feet of drifts and raises, and diamond drilling 1,111 feet of holes.

Wenatchee River district.—Knob Hill Mines, Inc., shipped 1,645 tons of gold ore from the Gold King mine to the Tacoma smelter. The ore was shipped to test the value in preparation for further mining.

FERRY COUNTY

Republic district.—Mines in the Republic district were again the main source of siliceous ore in the State. They produced a total of 60,168 tons, of which 42,245 tons were treated by cyanidation-concentration and 17,923 were shipped crude to the Tacoma smelter. Knob Hill Mines, Inc., operated throughout 1944 and continued to be the most important producer in the district and the leading silver and second-largest gold producer in the State. The company treated 42,245 tons of gold ore in its 400-ton combination cyanidation and concentration mill, from which 3,504 tons of concentrates rich in gold were produced and shipped to Tacoma for smelting. The gold bullion was shipped to the Seattle Assay Office. The ore treated in 1944 had about the same gold content as that treated in 1943 but a slightly lower silver content; all production came from underground operations. Development in 1944 amounted to completion of 185 feet of

shaft and 300 feet of drifts. Lessees again operated the Aurum group of properties and shipped 2,269 tons of gold ore and 11,621 tons of dump material to the Tacoma copper smelter. Everett and I. G. Hougland, a partnership, operated the Valley and Republic mines in 1944; the material shipped comprised highly siliceous gold tailings (2,698 tons) from the Republic mine and siliceous gold ore (1,335 tons) from the dump of the Valley mine, and all was shipped crude to the Tacoma copper smelter for flux.

OKANOGAN COUNTY

Cascade district.—A car of gold ore shipped to the Tacoma copper smelter from the Bodie mine comprised the only output from the Cascade district in 1944.

Loomis-Oroville district.—The Kaaba-Texas Mining Co. operated its Kaaba mine and 150-ton flotation mill throughout 1944 and was the only operation producing in the district. The ore treated was slightly lower in grade (averaging 2.3 ounces of silver to the ton, 0.08 percent copper, 1.78 percent lead, and 0.65 percent zinc) than that treated in 1943; however, mill recoveries continued high. Mill machinery, lacking during the first part of 1943, was installed during the latter part of 1943 and in early 1944, permitting operations on a three-shift basis an average of 5 days a week. An average of 75 tons of ore a day was treated during the period of operation in 1944. Development was confined to 14 feet of diamond drilling.

PEND OREILLE COUNTY

Metaline district.—Mines in the Metaline district received much attention during 1944. Several of the major mining corporations operating in western United States showed interest in the potential zinc-lead reserves of the district. Some located tracts of land along the zone of mineralization. The Bureau of Mines, through its program of core drilling, has established a wide area of mineralization, which when developed may justify much larger mining operations than now exist. In 1944 mines in the Metaline district continued to supply the major part of the State output of lead and zinc. The value of recoverable metal was \$2,961,173, compared with \$2,699,363 in 1943. The increase is attributable to a larger output of lead and silver and a higher average price for lead and zinc. The mines were not able to reach capacity output owing to shortage of labor; however, the lead output in 1944 was the highest on record and was due to a higher lead content of the ore treated.

The extensive drilling campaign undertaken in 1943 by the Bureau of Mines on the mineral-bearing areas controlled by the Pend Oreille Mines & Metals Co. and the American Zinc, Lead & Smelting Co. was continued throughout 1944 and was recessed in early January 1945.

The Grandview mine produced 97,543 tons of zinc-lead milling ore, from which 9,716 tons of lead and zinc concentrates were produced. The grade of the ore treated was somewhat higher than in 1943. According to the company printed annual report for the year ended December 31, 1944, development consisted of 7,297 feet of surface diamond drilling, 5,567 feet of underground diamond drilling,

and 1,395 feet of drifts and raises. Production and development were both curtailed as a result of the manpower shortage during the late spring and summer months.

The property of the Metaline Mining & Leasing Co. operated by the American Zinc, Lead & Smelting Co. produced 49,486 tons of zinc-lead ore, from which 4,990 tons of lead and zinc concentrates were produced. The ore treated was considerably higher in lead and slightly higher in zinc content than that treated in 1943; the increased lead content of the ore accounted for the gain over 1943 in total output of lead in both the district and the State. Development on Metaline Mining & Leasing Co. ground in 1944 consisted of 2,620 feet of drifts and 16,523 feet of diamond drilling. The printed annual report of the American Zinc, Lead & Smelting Co. regarding the property states:

During 1944 the Metaline Mining & Leasing Co. retired the first mortgage notes held by the American Zinc, Lead & Smelting Co.

Since the end of 1944 the American Zinc, Lead & Smelting Co. has effected a compromise on all indebtedness and has disposed of all its interest in the property. However, the company will continue to treat ore from the Grandview and Metaline properties in its 600-ton mill.

SNOHOMISH COUNTY

Index district.—Some copper ore was shipped direct to the Tacoma copper smelter from mines in the Index district in 1944.

STEVENS COUNTY

Bossburg district.—Russell Parker operated the Bonanza mine in 1944 until July, when the property was closed. Production amounted to 24 tons of lead ore shipped crude to the Bunker Hill smelter.

Colville-Middleport district.—The Victory Metals Corporation treated silver ore from the Old Dominion mine dump and zinc-lead ore from the Bruce mine in its concentrating mill in 1944. The lead concentrates produced were shipped to the Bunker Hill smelter, and the zinc concentrates went to the Sullivan electrolytic zinc plant. A car of zinc ore from the Northwest zinc mine was shipped to the Bauer (Utah) plant of Combined Metals Reduction Co. for treatment.

Deer Trail district.—Production from the Deer Trail district in 1944 comprised zinc-lead ore from the Cleveland mine milled by Zenith Mines, Inc.

Northport district.—The Sierra Zinc Co. operated its 90-ton flotation mill throughout 1944, treating zinc ore from the company Blue Ridge property during the first 8 months and zinc ore from the Deep Creek mine of the Jamison-Higginbotham Mining Co. during the last 4 months of the year. Production from the Blue Ridge property comprised 22,770 tons of zinc ore, from which 176 tons of lead concentrates and 2,148 tons of zinc concentrates were produced. The ore produced from the Blue Ridge property was slightly higher in grade than that treated in 1943. On February 15, 1944, the Bureau of Mines undertook a drilling campaign on the Blue Ridge property to explore surface indications of ore and concluded it on May 1. Six drill holes having a total length of 1,586 feet were completed. No minable width of ore was encountered in any of the holes; however, these holes provided

structural information useful in planning future drilling or exploration. The Jamison-Higginbotham Mining Co. began operations on July 1 at its Deep Creek mine, 6 miles southeast of Northport. Actual milling of the zinc ore from the property in the Sierra Zinc Co. 90-ton flotation mill was begun on September 1 and continued the remainder of the year. During the period of operation a total of 8,230 tons of ore was treated, from which were produced 550 tons of zinc concentrates averaging about 60 percent zinc and less than 1 percent lead. Other production in the Northport district in 1944 included lead ore shipped to the Bunker Hill smelter from the Gladstone Mountain and Electric Point mines, silver ore concentrated from the Frisco-Standard mine, and lead ore concentrated from the Red Top mine.

YAKIMA COUNTY

Naches River district.—The only production in Yakima County in 1944 was gold recovered from placer property.

GOLD, SILVER, COPPER, AND LEAD IN WYOMING

(MINE REPORT)

By RICHARD H. MOTE

SUMMARY OUTLINE

Summary	Page
Calculation of value of metal production	475
	476

SUMMARY

Of the gold, silver, copper, and lead mines in Wyoming only one—the Midas mine, Atlantic City district, Fremont County—produced in 1944. The ore output was 6 short tons, containing 20 fine ounces of gold and 3 fine ounces of silver, and was shipped to a smelter at Garfield, Utah.

All tonnage figures are short tons and "dry weight"; that is, they do not include moisture.

The value of the metal production herein reported has been calculated at the following prices.

Prices of gold, silver, copper, lead, and zinc, 1940-44

Year	Gold ¹	Silver ²	Copper ³	Lead ⁴	Zinc ⁵
	Per fine ounce	Per fine ounce	Per pound	Per pound	Per pound
1940	\$35.00	\$40.711+	\$0.113	\$0.050	\$0.063
1941	35.00	40.711+	.118	.057	.075
1942	35.00	40.711+	.121	.067	.093
1943	35.00	40.711+	.130	.075	.108
1944	35.00	40.711+	.135	.080	.114

¹ Price under authority of Gold Reserve Act of Jan. 31, 1934. Treasury legal coinage value of gold from Jan. 18, 1837, to Jan. 31, 1934, was \$20.67+ (\$20.671835) per fine ounce.

² Treasury buying price for newly mined silver.

³ 1940-41: Yearly average weighted price of all grades of primary metal sold by producers; 1942-44: Price includes bonus payments by Metals Reserve Co. for overquota production.

⁴ \$0.7111111.

The following table shows the annual output of ore from lode mines producing gold, silver, copper, and lead and the quantity and value of the metals recovered from both lode and placer mines in Wyoming from 1940 to 1944; it also gives the total production of metals from 1867 to 1944. About three-fourths of the total recorded value of the four metals is in copper, most of which was mined before 1924 in the Encampment district, in Carbon County, and the Hartville district, originally in Laramie County, now in Platte County.

Mine production of gold, silver, copper, and lead in Wyoming, 1940-44, and total, 1867-1944, in terms of recovered metals

Year	Ore (short tons)	Gold (lode and placer)		Silver (lode and placer)		Copper		Lead		Total value

GENERAL SUMMARY

Final figures on the recovery of nonferrous secondary metals from purchased scrap in 1944 reveal continuation of the high rate of production of material from secondary sources, with only slight declines in the recovery of some of the metals surveyed, and significant gains in the tonnages of the light metals aluminum and magnesium reclaimed from scrap. The fabrication of metal parts for war production resulted in the continued flow of most types of new scrap to wrought-alloy producers, ingot makers, and foundries, although a substantial decline was registered in recovery of both copper and zinc from new scrap, due to cut-backs effected in the ammunition program. However, the losses in recovery of copper and zinc from new scrap were almost balanced by gains in recovery from old scrap, mainly because of the return of large quantities of fired cartridge cases to the industry for remelting. In general, the ratio of new scrap to old scrap used was nearer the prewar level than in 1943, when unprecedented production schedules upset the balance between the use of the two types to a marked degree by the generation of an unusual volume of new scrap.

Salient statistics of nonferrous secondary metals recovered in the United States, 1943-44

Metal	New scrap		Old scrap		Total

¹ Revised figures.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

The value of metals recovered in 1944 from both new and old scrap was \$467,294,751, compared with \$507,924,702 in 1943. This decline was due to the drop in value of metals recovered from new scrap—from \$310,770,206 in 1943 to \$267,664,826 in 1944; in contrast, the value of metals reclaimed from old scrap rose from \$197,154,496 in 1943 to \$199,629,925 in 1944.

Secondary metals recovered as unalloyed metal, in alloys, and in chemical compounds in the United States, 1940-44, in short tons

¹ Revised figure.

² Data not available.

The importance of secondary metals in the mineral economy of the Nation has been demonstrated during the war years by the prominent position these metals have occupied in the war production program. Certainly, the role of secondary metals in the coming peacetime economy merits a constructive program of scrap salvage and consumption, in order that our mineral resources, both above ground and underground, may be utilized in the most efficient manner. This was forcefully brought out in a recent paper by Pehrson,² who reviewed the findings of a joint committee of geologists and mining engineers from the Geological Survey and the Bureau of Mines, that recently surveyed the mineral resources of our country.

The gist of the discussion regarding the eight nonferrous metals on which canvasses concerning secondary metal recovery are conducted was that for only one, magnesium, does the United States occupy a comfortable reserve position. Our reserve position in the other metals discussed in this chapter—aluminum, copper, lead, tin, zinc, nickel, and antimony—is not so fortunate. Commercial reserves, expressed in years' supply remaining in 1944 at the prewar rate of use, are as follows: Copper, 34 years; zinc, 19 years; lead, 12 years; aluminum (bauxite), 9 years; antimony, 4 years; nickel and tin, less than 1 year. Our known deposits of the last two elements have always been negligible, and war-induced explorations have not disclosed appreciable new commercial reserves. It may be readily seen that the enormous consumption of materials since 1900 has seriously depleted reserves of minerals on which a great part of the industrial structure of the Nation has been built.

Some waste of resources still occurs through the use of inadequate techniques, but industry is to be commended for technologic improvements in the past few years leading to the increased recovery of secondary metals. Research and engineering and the scrap-metal industry should be recognized as the greatest conservational forces working today toward the preservation of our mineral economy.

² Pehrson, E. W., *The Mineral Position of the United States and the Outlook for the Future*: Min. and Met., vol. 26, No. 460, April 1945, pp. 204-214.

Many of the improvements in metal technology during the war years have been the direct result of orders issued by the War Production Board in effecting transition of the metal industries to a war basis. The most far-reaching effects were produced by the various orders that made mandatory the segregation of specified types of nonferrous scrap. The orders limiting the use of certain metals caused many companies to branch out into new manufacturing fields, with the salutary result that they had to install the most modern methods to utilize their plants in the war program. In addition, the reporting requirements set by the War Production Board and the Office of Price Administration, which were instituted by those agencies for the purpose of obtaining working information, proved to be the means of bringing to the attention of many operators of smaller metal-working establishments the value of keeping adequate records on consumption and production of materials, which would make more feasible the preparation of operating-cost data.

POSTWAR OUTLOOK

Owing to the enormous need for both capital and consumer goods that has accumulated during the war years, the demand for most types of nonferrous metal scrap should continue near the wartime level. Moreover, the anticipated decline in primary metal production when premium payments are discontinued should place a larger proportion of the supply burden on secondary sources. This is certainly true of the metals (copper, zinc, lead, and antimony) with long-established fields of use because manufacturers will demand them to recapture civilian markets lost during utilization of their plants in war production. The demand for the light metals aluminum and magnesium in the immediate postwar period depends largely upon the extent to which they replace other materials in manufacture and construction; consequently, future demand for aluminum and magnesium scrap remains obscure.

The prospect for a balance of supply of scrap materials against demand appeared to be good. Earlier fears that enormous quantities of industrial scrap would be turned into the market upon the termination of war contracts were allayed somewhat as military and naval authorities collaborated with the War Production Board in outlining a more gradual conversion to civilian production. There was no evidence by the end of the year, or even after the end of the war in Europe, that any disturbing amount of nonferrous scrap would be forthcoming from manufacturing plants being forced to reconvert; instead, as metal stock and semifinished material were shown to be surplus, they were allocated quickly to other consumers, and clean-up scrap found a ready market.

During 1944 and the early part of 1945 it was the general practice of both the Army and the Navy to make a special effort to return only fired cartridge cases to this country from overseas. Other types of battlefield scrap were considered too difficult to segregate and prepare and too bulky to permit economical reshipment and were returned only when readily available at the ports. In addition, it was believed that foreign markets could more readily absorb the material; just before the end of the war in Europe a substantial tonnage of cartridge cases was allotted to France in lieu of virgin copper.

Stocks of wrecked aircraft scrap steadily increased in dealers' yards and Metals Reserve Company stock piles throughout 1944, and

the effective utilization of this material, with the potential supply of such magnitude, threatened to become the biggest single problem of the secondary metal industries. However, a new method of using such scrap was being developed early in 1945 that offered some prospect of solving this problem. This, process, developed by the Aluminum Ore Co., employs some of the solution used in the Bayer process for bauxite to dissolve the aluminum from wrecked and war-weary aircraft scrap in huge tanks built especially for the purpose. The aluminum emerges as alumina for further treatment in primary reduction plants; and the other elements in the scrap—such as magnesium, copper wire, and steel rivets—are raked from the tank periodically for sorting and possible resale. The process is still in the experimental stage, and costs for commercial application have not been determined.

In setting up the Surplus War Property Administration it was decided that, in the case of scrap, the owning agency should handle its disposal. The salvage agencies of both the War and Navy Departments have been active in channeling all types of scrap back to consumers to facilitate production, thereby reducing the amount of material remaining to be sold by these departments after the war.

SCOPE OF REPORT

Statistics on scrap and secondary metal for 1944 were accumulated from a number of canvasses covering all known consumers of purchased nonferrous scrap metals and a representative group of dealers. Reports were received monthly or annually from 368 plants classed as remelters, smelters, or refiners; from 1,077 plants classed as rolling mills, foundries, chemicals works, or other manufacturers; and from a representative group (approximately 2,100) of the 4,500 dealers in nonferrous scrap metal. The larger consumers of scrap in the secondary lead and zinc industries, as well as the selected group of 2,100 dealers, were canvassed monthly by the Bureau of Mines, but figures for consumption of aluminum scrap and ingot production by makers of aluminum ingot and the detailed break-down of copper alloys produced by brass ingot makers, were taken from monthly surveys conducted by the War Production Board. All other figures in this report were derived from annual canvasses conducted by the Bureau of Mines.

"Secondary metals" are metals or alloys recovered from scrap and residues. The term "secondary" applies only to the source of metal and has no relation to the type of product recovered, either as to degree of purity or impurity or physical characteristics.

"Purchased scrap" means all scrap that entered any plant in scrap form and includes scrap treated for customers upon a toll basis or conversion agreement and interplant transfers of scrap. Scrap salvaged by railroads from line operations and melted in their own foundries and that melted by Navy Yard foundries which originated in salvage operations are included in this category, as a definite recovery of secondary metal can be counted from the melting of such scrap.

"Interplant transfers" are those made between separate plants owned or operated by the same parent company but not located on the same ground. A transfer of scrap from a machine shop to a

foundry at the same plant location is not an interplant transfer, and such "home scrap" is not included in this report.

"New scrap" is defined as the refuse produced during the manufacture of articles for ultimate consumption, including all defective finished or semifinished articles that must be reworked. Typical examples of new scrap are defective castings, clippings, punchings, turnings, borings, skimmings, drosses, and slag.

"Old Scrap" is defined as scrap consisting of metal articles that have been discarded after serving a useful purpose. Typical examples of old scrap are discarded trolley wire, battery plates, railroad-car boxes, fired cartridge cases, automobile crankcases, used pipe, and lithographers' plates.

SECONDARY ALUMINUM¹

The year 1944 saw the recovery of aluminum from scrap rise to a new record, totaling 325,645 short tons valued at \$93,264,728 compared with 313,961 tons valued at \$90,546,352 in 1943. Values were calculated on the basis of the replacement value of primary aluminum at 14.32 cents a pound in 1944 and 14.42 cents in 1943. The quantity recovered has risen steadily each year since 1938, under the impetus of enormous supplies of new industrial scrap made available from war production activities.

Secondary aluminum¹ recovered in the United States, 1943-44, in short tons

Secondary aluminum recovered			Recoverable aluminum-alloy content of scrap		
Form of recovery	1943	1944	Kind of scrap processed	1943	1944
As metal.....	5,926	2,336	New scrap:		
Aluminum alloys.....	305,357	320,040	Aluminum-base ²	280,065	302,230

In zinc-base alloys.....	219	1,187	Zinc-base.....	78	87
In chemical compounds.....	1,180	1,616		280,867	302,746
	313,961	325,645	Old scrap:		
			Aluminum-base ²	32,414	22,359
			Copper-base.....	540	440
			Zinc-base.....	140	100
				33,094	22,899
				313,961	325,645

¹ In accordance with common usage, the term "aluminum" covers aluminum alloys, and the figures include all constituents of the alloys recovered from aluminum-base scrap.

² Recoverable aluminum content of new aluminum-base scrap was 261,282 tons in 1943 and 281,804 tons in 1944.

³ Recoverable aluminum content of old aluminum-base scrap was 29,714 tons in 1943 and 20,495 tons in 1944.

The production⁴ of realloyed (secondary) aluminum ingot continued its upward trend, totaling 214,879 short tons in 1944, compared with 196,373 tons in 1943 and 144,694 tons in 1942, and recovery of secondary aluminum in wrought products from purchased scrap at aluminum rolling mills increased from 53,080 tons in 1942 to 121,827 tons in 1943, then declined slightly to 116,582 tons in 1944. The continued use of large amounts of scrap in wrought-aluminum products

⁴ The term "secondary aluminum" is used broadly to cover aluminum and aluminum alloys, including the weight of alloy constituents, such as copper, silicon, magnesium, and others.

⁵ Figures for aluminum scrap consumed by smelters and aluminum ingot produced were derived from a survey conducted by the War Production Board.

was made possible by simple methods of marking sheet, tube, and shapes with the appropriate alloy number, so that the number would appear on almost every piece of industrial scrap of any size and greatly facilitate identification and segregation of alloy types.

Production of secondary aluminum and aluminum-alloy products in the United States, 1942-44, gross weight, in short tons

	1942	1943	1944
Secondary aluminum ingot: ¹			
Pure aluminum (98.5 percent)	2,924	715	1,151

Aluminum in chemicals	480	448	8,660
	1,668	1,180	1,616

¹Gross weight of alloys, including copper, silicon, and other added elements; total secondary ingot consumed 565 tons of primary aluminum in 1942, 8,471 tons in 1943, and 8,792 tons in 1944.

²"Primary grade" ingot is a new classification of ingot made from scrap with primary aluminum added to bring specifications of the alloys equal to those made entirely from primary metal.

³Includes 18,552 tons produced on toll in 1943 and 9,089 tons in 1944.

⁴Combined with primary aluminum in the products of aluminum rolling mills.

⁵Does not include production measured as ingot for graining, powder, atomizing, or chemical purposes.

The acceptance of secondary aluminum in fields formerly supplied by primary aluminum increased in 1944, as it was demonstrated that aluminum alloy ingot meeting the most rigid specifications could be supplied from remelt materials. This was due in part to general improvement in smelting methods but was more directly the result of extreme care in the handling of scrap, as fabricating plants, dealers, and smelters all bent their efforts toward solving the problems of segregation of alloy types and the holding of impurities such as iron to a minimum.

In spite of these technologic advances, the tonnage of wrought-aluminum alloys made by secondary smelters declined from 45,063 tons in 1943 to 21,651 tons in 1944 because most of the segregated wrought scrap was being channeled back to primary plants. The secondary smelters consumed greater amounts of casting-alloy scrap and turnings and borings, and their production of ingot was heavier in such groups as the casting and piston alloys, and ingot for deoxidation. As some of the restrictions on the melting of aluminum, which had been in force since January 1942, were lifted in September of 1944, larger amounts of scrap were consumed in such products as castings, aluminum chemicals, and powder in the latter part of the year.

Makers of secondary aluminum ingot used 8,792 tons of primary aluminum and 6,822 tons of alloying ingredients, such as copper and silicon, in addition to aluminum scrap. Only a slight increase was made in the quantity of aluminum scrap consumed, from 352,124 tons in 1943 to 354,182 tons in 1944. Of the 1944 total, 220,553 tons or 62 percent, was used by ingot makers at 55 plants. As the restrictions of

War Production Board Order M-1-d regarding the melting of aluminum were relaxed on September 22, smelters were no longer designated as "limited" or "approved." Primary producers used 121,290 tons at 22 aluminum rolling mills, extrusion plants, and smelters; the remaining 12,339 tons were used by foundries, chemical works, and miscellaneous manufacturers. The downward trend in the use of old scrap, such as obsolete castings and old sheet and utensil, was continued through 1944, with only 25,223 tons of old scrap used compared with 34,266 tons in 1943 and 43,248 tons in 1942. The supply of new scrap, however, was plentiful, and 328,959 tons were used in 1944—an increase of 3 percent over the 317,858 tons consumed in 1943.

Consumption of purchased aluminum scrap in the United States in 1944, gross weight, in short tons

¹ Includes 10,123 tons treated on toll.

Scrap-metal dealers increased their purchases of aluminum scrap again in 1944, with receipts of all types in their yards rising to 186,171 tons compared with 145,975 tons in 1943, a gain of 28 percent. Shipments by dealers to consumers totaled 156,804 tons during the year, a substantial increase over the 1943 figure of 130,295 tons, and more than 55 percent greater than the 100,796 tons shipped during 1942. Stocks in dealers' yards rose steadily from 25,072 tons on January 1 to 55,812 tons at the end of the year. A comparison of these figures with the 8,720 tons in dealers' hands at the end of 1942 shows the rate at which stocks of this scrap have accumulated. Dealers' prewar stocks of aluminum scrap averaged approximately 4,000 tons.

During the first 9 months of 1944, dealers bought great quantities of wrecked aircraft scrap. A special survey by the Bureau of Mines of a large number of dealer purchases showed that the average price paid for it was about \$12.50 a ton. However, purchases of this material slackened considerably after October 2, 1944, when the Surplus War Property Administration ruled that bids below \$25 a ton would be rejected and the scrap stock-piled by Metals Reserve Company. Wrecked aircraft scrap purchased by dealers at such low prices was one of the contributing factors in the rise in aluminum scrap inventories, since there was a limited smelter demand for this type of material. As it presented a preparation problem of some magnitude, the indications were that the dealers planned to hold it until the manpower

situation was easier, or until new technologic developments enhanced its future value.

In an effort to solve a storage problem, the Navy Department built melting furnaces at six naval air stations for melting wrecked aircraft scrap into low-grade ingot. Approximately 1,600 tons of this ingot were sold by the Naval Material Redistribution and Disposal Authority during the latter part of the year.

It appeared that wrecked aircraft scrap would not be returned to the United States from world-wide battle areas in large quantities, owing to the lack of transportation and manpower, the expense, and the inaccessibility of crashed or damaged planes. However, considerable tonnages of aircraft scrap promised to accumulate from operations in and near this country, as was demonstrated by steadily rising inventories of this material in dealers' yards and Metals Reserve Company stock piles. There also remained the uncertain quantity evolved by the removal from service of thousands of planes after the war. In view of this outlook of certain oversupply, research was under way at the end of the year to work out a satisfactory method of utilizing such scrap, promising results being obtained shortly afterward.

Consumers' stocks of purchased aluminum-based scrap in the United States at end of year, 1943-44, gross weight, in short tons

Scrap Item	On hand—	
	Dec. 31, 1943	Dec. 31, 1944
Castings and forgings.....	785	1,689
Sheet, turnings, clippings, etc.....	7,843	12,367
Miscellaneous aluminum and dross.....	3,109	1,611
	11,737	15,667

As the supply of aluminum became more plentiful during 1944, the War Production Board issued a number of amendments to, and revocations of, the various restrictive orders, each designed to permit the wider use of aluminum, specifically lifting the burden of restrictions from aluminum foundries. C. M. P. Regulation 5, Direction 1, as amended April 26, stated that any foundry may melt aluminum scrap in the form of obsolete or defective patterns furnished by the prospective purchaser of the new pattern without prior authorization. Shortly after, on May 3, the War Production Board rescinded an order issued on February 19, 1942, which had instructed foundries to procure all their requirements of aluminum alloys from secondary smelters. Finally, on September 22, Order M-1-d was amended, so that nearly all restrictions on the receipt and use of aluminum scrap were lifted, and mandatory segregation of aluminum scrap was no longer required. This last amendment brought about a large and immediate increase in purchases of scrap by foundries.

The ceiling price for secondary aluminum ingot, high-grade, which had dropped to 12.5 cents on December 18, 1943, remained at that price throughout 1944, although smelters were permitted to charge 15 cents for the primary-grade ingots, containing 30 percent to 50 percent primary aluminum. During most of the year the actual selling prices were less than ceiling, indicating that production was

pace demand under the Controlled Materials Plan. As the supply of aluminum scrap of all types except the purer grades was more than adequate during the year, the maximum price declined to 10 cents a pound in December, although most sales were consummated at prices below ceiling. However, premium prices were allowed for segregated scrap that had been bundled or briquetted and for foil suitable for use in paints and chemicals.

Dealers' buying prices for cast-aluminum scrap in New York averaged 4.04 cents per pound in 1944, the lowest yearly average since 1932 and 2.95 cents per pound below the 1943 average of 6.99 cents. The yearly average price for this scrap has decreased steadily since 1941. Monthly average quotations opened at 5.03 cents in January and were down to 4.25 cents by April. This price was maintained until August, after which the monthly average dropped gradually to the year's low point of 3.12 cents in December. The yearly average price for new aluminum clippings was 5.12 cents per pound compared with 7.72 cents in 1943. The yearly average for this scrap also has dropped steadily since 1941. The monthly average gradually decreased from 5.75 cents in January to 4.87 cents in September and remained at the latter figure through December.

SECONDARY MAGNESIUM

During 1944, 14,185 short tons of secondary magnesium (including alloying ingredients) were recovered from scrap, representing an increase of 24 percent over the 11,404 tons reclaimed in 1943. The value of this secondary magnesium was \$5,815,850 computed at 20.50 cents a pound in 1944, compared with \$4,798,803 computed at 21.04 cents a pound in 1943.

Capital and consumer goods and war matériel made of magnesium still had not begun returning to foundries and secondary smelters in any quantity, and recovery of magnesium from old scrap amounted to less than 2 percent of the total. Owing to the machinability of magnesium alloys and to the fact that many plants were just learning to produce articles from them, the generation of borings, turnings, and savings was out of proportion to normal practice, and the tonnage of this type of scrap used constituted 89 percent of the total.

A total of 14,419 tons of secondary magnesium alloy ingot was produced by secondary smelters during 1944. This ingot required the blending of 3,202 tons of primary magnesium and minor tonnages of other alloying constituents, in addition to the purchased scrap consumed.

Secondary magnesium recovered in the United States, 1943-44, in short tons

From new scrap.....	11,404	14,185
From old scrap.....	11,254	13,976
	150	209

¹ Figures include secondary magnesium incorporated in primary magnesium ingot.

Because of trouble in certain foundries with contamination of foundry sand by tiny particles of magnesium oxide and the resulting surface defects on castings, there was a general reaction against the use of home scrap, such as runners, gates, and risers in foundry melts, and this material was shipped to smelters in some instances, its use by these consumers depending upon its physical condition. However, foundry operators reported the recovery of 235 tons of secondary magnesium from purchased scrap in magnesium-alloy castings in 1944. This represented a decline of 28 percent from the 327 tons recovered in castings in 1943, indicating a general improvement in technique, since the greater part of the casting scrap used in the 2 years was new scrap, such as rejected castings.

The consumption of magnesium scrap in chemical and incendiary uses showed an astonishing gain in 1944, the recovery of magnesium in such applications increasing from 33 tons in 1943 to 541 tons in 1944. Chemical applications included the use of magnesium scrap in fluxing compounds, in the Grignard reaction, and in the production of magnesium nitrate and chloride, the incendiary uses being in the production of war material such as flares and incendiary bombs. In spite of the employment of magnesium scrap for such a wide variety of purposes, the fire hazard presented by its storage, especially in the finely divided state, prevented full utilization of this material, because large quantities were disposed of by burning to avoid the risk incident to storage.

Stocks and consumption of magnesium scrap in the United States in 1944, gross weight, in short tons

Kind of scrap	On hand—		Consumption during 1944
	Dec. 31, 1943	Dec. 31, 1944	
Cast scrap.....	32	31	1,706
Solid wrought scrap.....	14	3	129
Borings, grindings, drosses, etc.....	279	60	15,179
	325	94	17,014

Owing to the difficulties experienced by the War Production Board in obtaining full production of magnesium materials, because of the general reluctance of industry to use this relatively new member of the commercial metal family, action was taken during October 1944 to ease the Government restrictive controls over the metal, including scrap and secondary magnesium, by the issuance of Supplementary Limitation Order L-2-C. Although the reporting requirements were retained regarding use and production of material for purposes of information, the new order had the effect of assuring manufacturers that magnesium could be obtained without the involved procedures necessary in obtaining most other metals. The order stated that "persons wishing to acquire magnesium or magnesium products may place purchase orders on their supplier, without securing approval * * *."

Maximum prices on magnesium scrap and remelt ingot were continued through 1944 without change, having been established under Maximum Price Regulation 302 on January 20, 1943. New segregated solids were exempt from price ceilings, but segregated

borings had a maximum price of 9 cents a pound, with mixed borings at 8 cents and mixed solids at 12 cents. The ceiling on class A remelt ingot was set at 21.5 cents a pound.

SECONDARY COPPER AND BRASS

The recovery of secondary copper in 1944 totaled 950,942 short tons valued at \$224,422,312, a decline of 12 percent from the 1,086,047 tons valued at \$256,307,092 recovered in 1943. The value of copper has remained at 11.8 cents a pound, exclusive of Metals Reserve Company bonus payments, for the past 4 years.

Recovery of copper from old scrap, instead of decreasing as was expected, climbed to 456,710 tons, or 7 percent more than the 427,521 tons recovered in 1943. The principal cause of this increase was the expeditious handling of fired cartridge cases, of which 136,448 short tons were used during the year. Salvage agencies of the War and Navy Departments bent every effort to return cartridge cases to the industry, in order that the ammunition program might not suffer from a shortage of materials, and Army sources alone reported the sale of over 100,000 tons, more than half of which came from overseas. In addition, nonferrous scrap dealers were instrumental in collecting a large amount of old scrap, handicapped as they were by shortages of manpower, gasoline, and tires.

Secondary copper recovered in the United States, 1943-44, in short tons

Secondary copper recovered			Recoverable copper content of scrap

	1,086,047	950,942		427,521	456,710
				1,086,047	950,942

Cut-backs in the manufacture of munitions in the late summer and fall months caused a 25-percent drop in the recovery of copper from new scrap—from 658,526 tons in 1943 to 494,232 tons in 1944. Although the use of new scrap in 1944 declined from that in the previous year, it still was much higher than in a normal prewar year, indicating that the ratio of old copper scrap to new scrap used would be even higher after the return of the Nation to a peacetime economy. Certainly, large quantities of consumer goods, which had outlived their normal span of life during the war years, were to be scrapped as soon as new products appeared on the civilian market.

The production of refined copper (electrolytic grade) from scrap fell to 93,046 tons in 1944, a loss of 28 percent from the 128,836 tons produced in 1943. This decrease was attributed to the lower quantity

of purchased low-grade residues and refinery brass available for treatment, because brass ingot makers processed their own residues and skimmings in cupolas to produce a form of black copper suitable for stock alloying. Of the 12 refineries that reported the use of scrap, 9 were producers of primary copper. The total recovery of unalloyed copper from scrap declined from 137,883 tons in 1943 to 102,135 in 1944.

Analysis and production of secondary copper and copper-alloy products in the United States, 1943-44

³ Production of this item combined with 85-5-5-5 group in 1944.

⁴ Gross weight of secondary brass and bronze in commercial shapes. Includes 422,818 tons of copper, 246 tons of nickel, 4,390 tons of lead, 282 tons of tin, 177,255 tons of zinc, and 18 tons of aluminum in 1943; and 367,425 tons of copper, 275 tons of nickel, 4,210 tons of lead, 330 tons of tin, 156,830 tons of zinc, and 79 tons of aluminum in 1944.

⁵ Gross weight of secondary brass and bronze castings. Includes 91,548 tons of copper, 18 tons of nickel, 7,540 tons of lead, 5,838 tons of tin, and 4,228 tons of zinc in 1943; and 118,391 tons of copper, 29 tons of nickel, 6,887 tons of lead, 7,493 tons of tin, and 7,765 tons of zinc in 1944.

The commercial production of brass and bronze ingot climbed to a new record of 518,261 short tons (gross weight) in 1944, an increase of 6 percent over the 488,185 tons produced in 1943. The 518,261 tons of ingot contained 423,027 tons of copper, of which 46,533 tons came from primary refined copper and the rest from scrap. Total shipments of ingot during the year were 511,465 tons, so that stocks at producers' plants increased from 8,777 tons (revised) at the start of the year to 15,573 tons on December 31. Seventy-five plants produced brass and bronze ingot for sale in 1944, and two foundries made ingot for their own use. Copper shot and anodes and copper-nickel alloys were made at two additional plants that did not produce brass ingot.

The arrangement that had been made in 1943 to have brass ingot makers pour brass-mill billets and cakes from their scrap melts was continued in 1944 in four plants. These smelters produced 19,558 short tons of yellow rod brass, 9,056 tons of yellow brass, 2,417 tons of Muntz metal, 660 tons of commercial bronze, 647 tons of manganese bronze, 231 tons of tin bronze, 112 tons of red brass, and 66 tons of aluminum bronze. One of the plants had set its own brass mill in operation early in the year, so not all of the material listed was shipped to other plants for rolling and fabricating.

The operations of brass mills declined considerably from the 1943 level. A total of 540 tons of unalloyed copper products and 509,153 tons of brass and bronze sheet, rod, and tubing was recovered from scrap at 44 plants during 1944. As brass mills worked under a blanket scrap allocation from the War Production Board, they had little difficulty in obtaining all the scrap needed, working as they were on reduced production schedules. As a result, large tonnages of "brass-mill scrap" were used by ingot makers to help supply the augmented demand for their product.

Foundries produced 143,665 tons of brass and bronze castings from scrap during the year, an increase of 31 percent over the 109,472 tons made in 1943. By far the greatest part of this tonnage consisted of bronze railroad bearings remelted in railroad foundries and in plants of bearing companies on a toll basis.

Consumption of purchased copper scrap in the United States in 1944, gross weight, in short tons

The total consumption of purchased copper and brass scrap in 1944 was 1,407,860 short tons, a substantial decline from the record quantity of 1,533,823 tons used in 1943. Brass ingot makers and refineries decreased their consumption 8 percent to 727,873 tons, and the use of scrap by brass mills declined 16 percent to 511,661 tons, owing to the reduction in the manufacture of munitions. However, the brass and bronze foundries and other manufacturers that used purchased copper-base scrap raised their consumption by 26 percent to 168,326 tons. The remelting of fired cartridge cases skyrocketed from approximately 8,000 short tons in 1942 to 46,872 tons in 1943, then to 136,448 tons in

44. Brass mills consumed more than half of the total used in 44, most of the remainder being used by brass ingot makers, although cartridge cases were used for a number of other purposes, even coinage of the 1-cent piece, by admixture with primary copper.

As the exigencies of maritime transportation demanded prompt turn of vessels dispatched to Western European ports and Pacific seas, little opportunity was afforded for the return of overseas battle scrap. Ships unloading near battle areas could not wait to take on scrap, even if they were collected and ready, and the Army had itself too busy furnishing supplies to the front to bother with collection. However, Army sources stated they had somehow managed the return of approximately 55,000 short tons of fired cartridge cases, 764 tons of other copper and brass scrap, 2,249 tons of aluminum scrap, 1,150 tons of other nonferrous metal scrap, and 9,700 tons of iron and steel scrap during the year.

War Production Board authorities stated that the supply and consumption of copper-base scrap were in balance during all of 1944. According to the monthly surveys conducted by the Bureau of Mines, dealers' inventories showed remarkably little variation, and the supply was just tight enough to maintain prices at ceiling (with some slight exceptions) without causing any inconvenience, since it was augmented efficiently by bonus-induced primary copper production to balance the raw material situation effectively. Brass-ingot makers, working against an unprecedented demand for ingot and denied the blanket scrap allocations granted to brass mills, used 46,533 tons of primary copper, 11,262 tons of pig tin, and proportionate quantities of other refined metals to fill material requirements.

Consumers' stocks of purchased copper-base scrap in the United States at end of year, 1943-44, gross weight, in short tons

Other scrap and residues.....	34,567	24,175
Total.....	101,775	80,940

¹Revised figures.

Consumers' inventories of copper and brass scrap dropped 20 percent from 101,775 tons (revised) at the beginning of the year to 80,940 tons on December 31, 1944.

Shipments of copper and brass scrap by dealers to consumers during the year reached 501,493 tons, a gain of less than 1 percent over 496,943 tons shipped in 1943. A good percentage of the material collected by dealers was brass-mill scrap, although the normal route for this type of scrap, consisting of clips, punchings, and turnings, would be direct from the generators to the brass mills, since only the brass mills were normally allowed to melt it.

The ceiling prices on brass and bronze ingot were revised slightly on April 1, 1944. Upward revisions were made at that time in the prices of some types of ingot, including 85-5-5-5 at 13.00 cents a pound instead of 12.25 cents, and 80-10-10 at 15.75 cents instead of

14.25 cents; among the types whose price remained unchanged were yellow brass at 10.00 cents a pound and 88-10-2 at 16.50 cents.

Maximum prices for copper and brass scrap were revised on January 25, 1944, reducing the selling prices of five different grades of brass scrap on sales to copper refiners and ingot makers (these price changes were later revoked, on April 24th). At the same time, the Office of Price Administration announced specific maximum prices for two grades of scrap not previously priced, bringing to 48 the total number of scrap items covered by Maximum Price Regulation 20.

Ceiling prices for the basic copper-scrap items were unchanged, with No. 1 wire and heavy copper at 9.75 cents a pound, No. 2 wire and mixed heavy copper at 8.75 cents, and No. 1 composition at 9.00 cents a pound f. o. b. Scrap generated from the fabrication of brass stock produced by brass mills was officially designated as "brass-mill scrap" and maximum prices were first established on June 18, 1941. In 1944 the list contained 32 different classes, with a separate price within each class for clean heavy scrap, rod ends, and clean turnings. In general, brass-mill scrap could be sold only to dealers and brass mills, although allocations were made to other consumers during 1944.

The average dealers' buying price for No. 1 copper scrap at New York, which had held at 9.37 cents a pound throughout 1942 and 1943, continued until August 1944, when the market broke slightly because of optimism over the expected early termination of hostilities in Europe. The year's low point for this grade of scrap was reached in October at 9.13 cents, but the price rebounded to 9.37 cents by the end of the year, making the yearly average 9.34 cents. The price for No. 1 composition scrap during 1944, as in the previous year, was constant at 8.87 cents a pound.

Although the allocation of all copper and copper-base materials was continued through 1944, the scrap situation was improved to such an extent by the latter part of the year that complete allocation was unnecessary. Brass mills were granted blanket allocations for scrap, and other consumers who found themselves in need of a specific item or tonnage were quickly assisted by spot allocations. The rigid copper-conservation program was gradually relaxed, as far as use of copper materials was concerned, by the issuing of various amendments to existing conservation orders. However, complete relaxation of controls on copper was felt to be an impossibility until the end of the war, and the concessions made to civilian use provided for the release of only a minor tonnage of materials.

SECONDARY NICKEL

The total recoverable nickel content of nonferrous scrap used in 1944 was 4,321 short tons valued at \$3,024,700, a loss of 37 percent from the 6,917 tons valued at \$4,841,900 in 1943. As in the 3 previous years, the value was calculated at 35.0 cents a pound, the spot-delivery price of electrolytic nickel, including duty. This large decrease in recovery was due almost entirely to the operations of one company that consumed a great quantity of monel scrap gathered in a salvage campaign in 1943 but melted a relatively small tonnage of scrap in 1944.

Secondary nickel (nonferrous) recovered in the United States, 1943-44, in short tons

Includes only nonferrous nickel scrap added to cast iron and steel.

Recovery of nickel as metal declined from 796 tons in 1943 to 392 tons in 1944, and the production of secondary monel-metal pig, shot, and castings dropped from 3,336 tons in 1943 to only 1,100 tons in 1944. The production of copper-nickel pig and shot fell from 875 tons averaging 46 percent nickel in 1943 to 776 tons averaging 49 percent nickel in 1944. Consumption of all types of nickel scrap except pure nickel clippings declined from the previous year, the most important single factor in the loss being the drop in use of monel scrap, from 5,680 tons in 1943 to 2,997 tons in 1944. Consumers' stocks of nickel scrap increased from 1,509 short tons on December 31, 1943, to 2,045 tons on December 31, 1944, and stocks of nickel scrap in dealers' yards climbed from 811 tons to 1,994 tons in the same period.

This rise in dealers' and consumers' inventories, coupled with the decreased consumption of nickel scrap, graphically illustrates the

effect of the restrictive orders of the War Production Board regarding the use of nickel, even though steps were taken to relax the restrictions to a certain extent during the year. Nickel anodes, nickel salts, and plating solutions in inventory, which had been frozen since January 20, 1942, were released February 19, 1944, with the issuance of a Direction to Conservation Order M-6-b, delivery of such materials being restricted to persons who would use them in accordance with regulations. Another amendment to this order, issued on May 16, 1944, modified the rules governing the use of nickel solutions and nickel for necessary resistance materials. However, the order still stated that nickel may be freely used only in "implements of war," all ordinary domestic uses having been prohibited since April 1, 1942, and segregation of nickel scrap remained mandatory.

The maximum prices for nickel scrap remained unchanged throughout 1944, having been set at 26 cents a pound for pure nickel scrap and 20 cents a pound for new monel clippings on June 2, 1941. Dealers' buying prices for nickel clippings in New York were quoted at 20 cents a pound from the beginning of the year until August 30, when they dropped to 18.50 cents for the remainder of the year. Monel clips opened the year steadily at 16 cents and dropped to 14 cents on August 30 and then to 12.50 cents on October 5 for the remainder of the year. The average price of nickel clips was 19.50 cents and of monel clips 15 cents in 1944, compared with averages of 20.83 and 16 cents, respectively, in 1943.

There were no imports of nickel-bearing scrap reported in 1943 or 1944, but exports in 1944 amounted to 4,021 short tons, compared with 5,633 tons in 1943.

SECONDARY LEAD

Operations in the secondary lead industry remained at a high level during 1944, with 331,416 short tons of lead valued at \$42,421,248 recovered from scrap, compared with 342,094 tons (revised) valued at \$43,788,032 recovered in 1943. The decline was due entirely to the use of scrap items, such as battery-lead plates and drosses, which have a comparatively low lead content, as the total consumption of purchased scrap increased over the previous year. There were 61,700 tons of secondary soft lead produced compared with 58,591 tons in 1943, and the secondary lead content of antimonial lead also rose slightly, from 176,927 tons in 1943 to 180,818 tons in 1944. Secondary lead recovered in solder declined from 33,529 tons in 1943 to 22,245 tons in 1944, and the secondary lead content of type metals produced was 23,870 tons, showing little change from the 23,201 tons recovered in that product in 1943 and the comparable figure of 23,741 tons in 1942.

Examination of the figures reported reveals that, although the total recovery of lead from scrap declined in 1944, manufacturers of secondary lead products increased their tonnage of materials produced by adding larger percentages of primary metal than usual.

¹ Difference between gross weight of product and secondary metal content represents added primary metals or impurity content.

Of the total secondary lead recovered, 310,420 short tons were reclaimed from lead- and tin-base scrap; the remaining 20,996 tons were lead contained in secondary brass and bronze and reclaimed by remelting copper-base scrap. An additional 5,671 tons of lead in lead-base scrap was added to brass and bronze, bringing the total recovery of secondary lead in these products to 26,667 tons.

Consumption of purchased lead scrap in the United States in 1944, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap

	48,718	374,503	2,830	3,210	429,261

The gross weight of lead-base scrap consumed during 1944 amounted to 429,261 short tons, an increase of 2 percent over the 420,534 tons used in 1943. The use of battery-lead plates rose 17,193 tons, and that of drosses and residues 13,675 tons; but consumption of hard lead scrap dropped 3,995 tons, of cable lead scrap 9,380 tons, of solder scrap 5,257 tons, and of type metals 3,765 tons. The operations of remelters and smelters during the year were reflected in their use of lead-base scrap, which was steady in the first quarter, dipped sharply in April, then reached the year's low mark of 28,913 tons in June, after which it climbed to the peak in October, with 38,223 tons consumed.

Owing to the fact that the demand for lead constantly exceeded supply, Metals Reserve Company stock piles of the metal were gradually reduced until, at the end of 1944, their stock equaled approximately 1 month's supply. The consequent calls on the secondary lead industry to augment its production were met by smelters to the best of their ability; however, they were hampered by a shortage of labor for processing scrap, especially battery plates and drosses, and by unusually severe weather at the end of the year.

Percentage metals circulated in pig form among remelters and smelters during 1944 totaled 61,374 short tons, consisting of 36,951 tons of antimonial lead, 6,589 tons of soft lead, 6,322 tons of solder, 4,536 tons of type metal, 4,373 tons of lead-base bearing metal, 1,114 tons of tin babbitt, 905 tons of cable lead, 374 tons of silver-lead solder, 188 tons of remelt tin, 19 tons of pewter, and 3 tons of tin-bearing lead.

There was little change in inventories of lead scrap at consumers' plants, total stocks on December 31, 1944, being 71,598 short tons, compared with 71,500 at the end of the previous year. Because of continued demand, stocks of soft lead scrap remained at a very low point—probably a working minimum—being 2,457 tons at the end of the year or virtually the same as the 2,459 tons reported at the end of 1943. During the same period inventories of lead-base alloys declined 1,862 tons, but stocks of drosses and residues gained 1,962 tons. War Production Board authorities constantly campaigned for greater use of drosses and residues, in order to increase production of secondary lead, but manpower difficulties prevented smelters from fully utilizing their stocks of these materials.

Consumers' stocks of purchased lead-base scrap in the United States at end of year, 1943-44, gross weight, in short tons

Lead-base alloy.....	37,647	35,785
Dross and residues.....	31,394	33,356
	71,500	71,598

Scrap-metal dealers' stocks of lead-base scrap, which declined from 35,810 short tons on December 31, 1943, to a low of 31,023 tons at the end of May, showed a fairly steady increase for the rest of the year, amounting to 38,906 tons on December 31, 1944, the highest point in 3 years. Shipments of lead scrap by dealers to consumers totaled 253,165 tons in 1944, compared with 279,580 tons in 1943. As the demand on dealers for lead scrap was constant, the movement of scrap through dealer channels was also steady, with peaks of activity in January and October.

There were no changes in the maximum prices for lead scrap during 1944. Prices had been set on January 15, 1942, and with the addition of new basing points to the schedule were continued throughout 1943 and 1944. With the ceiling on primary pig lead at New York fixed at 6.50 cents a pound, the comparable price for heavy lead scrap, according to the formula delineated in the schedule, was the base price of primary lead less 0.55 cent, or 5.95 cents a pound.

Dealers' buying prices for heavy lead scrap remained 5.37 cents a pound throughout 1943 and 1944, there being no change in the monthly average quotation since August 1942. Dealers' buying prices for battery-lead plates at New York averaged 2.885 cents a pound for the year, ranging from 2.875 cents at the beginning of the year to 3 cents during the summer, then to 2.75 cents in October. Battery-plate smelting charges, which determined the dealers' net selling price, were not usually quoted, toll agreements for smelting scrap being prohibited except on authorization by the Office of Price Administration.

Although both scrap and secondary lead were subject to allocation by the War Production Board, no interference with the free movement of these materials was necessary. As a matter of fact, the only lead allocated was that from Metals Reserve Company stock piles, the greater portion of which was imported. However, as the supply of lead gradually grew scarcer during 1944, it was found necessary to issue on December 26 a drastic amendment to General Preference Order M-38 which prohibited the manufacture of a few additional articles from lead and restricted the use of lead in a long list of other articles to 30 percent, during a calendar quarter, of the amount used in those articles during the first 6 months of 1944. The amendment also restricted inventories of lead in all forms to a 45-day supply. Dealers in lead and lead scrap and refiners of lead, however, were specifically exempted from this provision of the Order.

There were no exports of lead scrap from this country reported in either 1943 or 1944. Imports from other countries jumped from 496 short tons (lead content) to 3,313 tons (lead content) in 1944.

SECONDARY TIN

Secondary tin recovered from scrap in 1944 totaled 32,589 short tons valued at \$33,892,560, a decline of 14 percent from the 37,820 tons valued at \$39,332,800 recovered in 1943. The value in both years was computed at 52 cents a pound.

Of the 32,589 tons recovered, only 4,245 tons were in the form of metallic tin. Detinning plants produced 3,751 short tons of pig tin from tinplate clippings and old tin-coated containers, and 471 tons (tin content) of secondary pig tin and 23 tons of tin foil were produced at various plants from tin-base scrap and residues. The total recovery of unalloyed tin from scrap was 4,245 short tons in 1944, compared with 5,252 tons in 1943. Recovery of tin in solder, in tin-base babbitts, in lead-base alloys, and in brass and bronze all declined from the 1943 figures, but the recovery in tin compounds at detinners' plants increased. As was the case in previous years, almost half of the tin reclaimed was contained in brass and bronze scrap, and more than half of that recovered went into brass and bronze, reflecting the consumption of tin-base scrap directly in the manufacture of these alloys.

Secondary tin recovered in the United States, 1943-44, in short tons

	37,820	32,589		37,820	32,589

Babbitt scrap and tin scruff and dross were the only types of tin-base scrap to be found in greater quantity than in 1943, as the flow of such types as block tin pipe, pewter, and tin residues was retarded from the effects of the tin conservation program, the manufacture of most materials of high tin content having been curtailed early in the war. The program for treating excess type metal, by the National Lead Co., for the account of Metals Reserve Company, was continued only through February, with 5 tons of tin reclaimed from this source in 1944.

The supply of all types of tin-base scrap was short, and ceiling prices prevailed throughout the year. The requirement of surrendering a used collapsible tube when each new tube of toilet preparations was purchased was rescinded on March 1, 1944, owing to the very low tin content of tubes manufactured during the collection period. Tin-reclamation operations on old tubes at the Government-owned plant of the Tin Salvage Institute were completed by the end of the year. In the salvage program carried out by this plant during

the 2 years and 8 months of activity, 4,494 tons of tubes were re-
ceived, and metal reclaimed amounted to 2,997 tons of alloys con-
taining 1,022 tons of tin, 1,928 tons of lead, and 47 tons of other
metals.

Endeavoring to ease the critical tin situation, the War Production Board issued several amendments to General Preference Order M-43 during the year. The two most important amendments were that of June 6, which permitted raising the tin content of solder to a point where the product could be used effectively, and that of December 30, which struck at the black market uses of tin, particularly in costume jewelry, by prohibiting the purchase of certain products for resale after December 30, 1944, and the sale of these articles after March 1, 1945.

	1,959	1,346

¹ Revised figures.

Quotations for dealers' buying prices of block-tin-pipe scrap at New York continued at 45.5 cents a pound throughout 1944, the same average as in the two previous years. The reports of scrap-metal dealers showed the shipment of only 1,262 tons of tin babbitt and pewter, and 155 tons of block-tin pipe to consumers during 1944, indicating that most shipments of tin scrap went directly to consumers from industrial sources. Imports of tin dross amounted to only 48 long tons in 1944 and 21 tons in 1943, compared with exports of tin dross and other tin-base scrap of 3,157 and 1,798 tons in the same 2 years.

Detinning plants.—During 1944, eight detinning plants were in operation: Johnston & Jennings Co., Metal & Thermit Corp. (three plants), Standard Metal Refining Co., Vulcan Detinning Co. (two plants), and a new plant in Birmingham, Ala.—the Southern Detinning Co. As was the case in 1943, these plants had a capacity for

handling a far greater tonnage of tin-plate clippings and used cans than was available for processing, so that nothing was lost by the cancellation in 1943 of the ambitious detinning-plant construction program.

Secondary tin recovered at detinning plants in the United States, 1943-44

In spite of the efforts of salvage agencies to promote more effective collection of old cans and the issuing of amendments to Conservation Order M-325 (restricting sales to other types of consumers and strengthening collection methods), the public response in the form of washed and flattened cans, ready for shipment, was disappointing. The amount of old cans treated by detinners fell from 175,870 long tons in 1943 to 146,976 tons in 1944, a decline of 16 percent. This loss was only partly offset by a slight gain in the tonnage of new tin-plate clippings processed. It is interesting to note that over 40,000 tons of prepared cans were shipped to detinners from Army posts, camps, and stations during 1944 or about 27 percent of the total amount treated.

Further declines in the average quantity of tin recovered per long ton of scrap were registered in 1944, due to substitution of electroplating for hot dipping of tin plate and to the use of lacquered and "bonderized" metal in many cans instead of tin plate. The average recovery of tin from new clippings declined from 25.12 pounds per long ton in 1943 to 23.36 pounds in 1944, and the recovery from old cans dropped from 22.58 pounds per long ton of cans treated in 1943 to 19.68 pounds in 1944.

Imports of tin-plate scrap in 1944 totaled 17,323 long tons, compared with 19,577 tons in 1943. Exports of tin-plate scrap, circles, waste-waste, and clippings rose to 4,435 long tons, contrasted with the comparatively low figure of 1,740 tons in 1943.

SECONDARY ANTIMONY

Secondary antimony recovered from lead- and tin-base scrap totaled 15,886 short tons valued at \$5,032,685 in 1944, a gain of less than 3 percent over the 15,483 tons valued at \$4,929,787 recovered during 1943. The value was computed at 15.84 cents a pound in 1944 and 15.96 cents a pound in 1943—the average selling prices for ordinary American-brand antimony in the 2 years at New York.

Secondary antimony recovered in the United States, 1943-44, in short tons

			Tin-base.....	312	303
				15,421	15,558
				15,483	15,886

The principal source of recoverable antimony in 1944, as in the past, was old battery plates. Remelters and smelters recovered 7,757 tons of antimony from this source during the year, an increase of more than 7 percent over the 7,215 tons reclaimed in 1943. The quantity of antimony recovered in antimonial lead increased from 9,255 tons in 1943 to 10,894 tons in 1944, but recovery of antimony in other lead- and tin-base alloys declined. This was due to two principal causes: The continued demand for antimonial lead for such purposes as replacement battery parts and the fact that the antimony content makes it desirable to process antimonial lead scrap back to antimonial lead, even when processed in primary lead plants. Almost 98 percent of the secondary antimony recovered in 1944 was reclaimed by remelters, smelters, and refiners and the other 2 percent by bearing manufacturers. Consumption of purchased scrap from which antimony was recovered may be found in the tables on consumption of lead-base and tin-base scrap in the sections of this chapter devoted to those metals, products in which antimony was recovered being included in the lead- and tin-products table. As far as could be determined, all antimony recovered from scrap remained in the alloyed state, none being regained as unalloyed metal or in chemical compounds.

All limitation on the antimony content of alloys had been removed in March 1943, and antimony was on the "free" list during all of 1944. However, owing to demand for antimony oxide for flameproofing, the supply of primary antimony became low by the end of the year, and allocations were reimposed early in 1945.

The ceiling price for antimony in alloy metals or metallic scrap, after having been last adjusted in April 1942, remained at 15.50 cents a pound of contained antimony. There was no regulation of prices for antimony in drosses, probably because of the small volume of this material that actually changed hands, since antimony skimmings collected in such processes as lead refining were retained until a sufficient quantity accumulated to justify making a "run" of antimonial lead. The maximum price for standard grade antimony remained 14.50 cents a pound at Laredo, Tex.

SECONDARY ZINC

Secondary zinc recovered in 1944 from purchased scrap and residues totaled 345,469 short tons with a value of \$59,420,668, calculated at

8.6 cents a pound, the average selling price for the year of all grade of refined zinc, not including bonuses paid by Metals Reserve Company. This total was 6 percent lower than in 1943, when 368,483 tons with a value of \$63,379,936 at 8.6 cents a pound were recovered

Secondary zinc recovered¹ in the United States, 1943-44, in short tons

	368,488	345,469			

¹ Zinc content.

The over-all decrease was caused by a 13-percent decline in secondary zinc recovered in brass and bronze from brass scrap. In contrast to the recovery from brass scrap, secondary zinc reclaimed from zinc-base scrap was 8,089 tons greater than the 124,433 tons recovered in 1943 and 8,026 greater than was salvaged in 1942. The 1944 gain was achieved by the secondary zinc industry in spite of the fact that the wartime uses of zinc, other than in brass, were mostly of a nature that would dissipate the metal. Galvanizing, smoke screens, pigments, and corroding plates for ships and boilers are all applications from which no salvage is expected. Although the zinc recovered from all copper-base scrap in 1944 decreased, that reclaimed from old scrap increased to 87,143 tons from 54,637 tons in the previous year, mostly as a result of increased recovery from fired cartridge cases. The decreased recovery from new copper-base scrap was attributable to cut-backs in the brass-manufacturing program during 1944.

The important decreases in recovery of zinc in 1944, aside from that in brass and bronze, were 7 percent in remelt metal and 6 percent in zinc sulfate. The largest gains in recovery were in chemical products, zinc recovered from scrap in zinc oxide rising 33 percent over the amount for 1943 and that in lithopone showing a gain of 23 percent over the 1943 figure.

Secondary zinc recovered in zinc dust totaled 22,753 tons compared with 22,336 tons in 1943, and that in redistilled slab increased to 48,582 tons in 1944 compared with 47,791 tons in the previous year. Zinc dust made from scrap amounted to 88 percent of the total domestic dust production from all sources, whereas the production of zinc oxide from scrap was only 6 percent of the total zinc oxide production from all sources. Most zinc dust is distilled from scrap in secondary plants, one reason for this being that the retorts used in

Smelting zinc from ore are too small and closely spaced to be conveniently used with the steel boxes employed for condensing zinc dust. The scrap was distilled at 21 smelters in 1944. Of these, 5 made both distilled slab and zinc dust, 12 made slab only, and 4 produced dust with no slab. Three plants that had produced slab in 1943 distilled scrap in 1944, and 1 1943 zinc-dust producer had no dust production in 1944.

Production of secondary zinc and zinc-alloy products in the United States, 1943-44, gross weight, in short tons

Product	1943	1944
Distilled slab zinc.....	48,215	49,037
Zinc dust.....	22,788	26,511
Spelter.....	7,406	7,741

Die-cast and die-casting alloys.....	2,617	1,786
Working stock.....	591	594
Waste zinc.....	909	1,737
Secondary zinc in chemical products.....	31,610	36,738

¹ Contains small tonnages of zinc anodes.

Secondary zinc recovered at 42 chemical plants in 1944 totaled 36,624 tons compared with 31,610 tons in the previous year. The chief increases were 2,610 tons in lithopone and 1,701 tons in lead-free zinc oxide. Secondary zinc recovered in miscellaneous chemicals including zinc carbonate increased 953 tons in 1944.

In addition to the chemical plants and distillers, 98 remelters, including brass-ingot makers, zinc smelters and scrap-metal dealers, and 107 foundries and other manufacturers consumed purchased zinc scrap in 1944.

Consumption of purchased zinc scrap in the United States in 1944, gross weight, in short tons

Scrap item	Remelters, smelters, and refiners		Manufacturers and foundries		Total scrap used
	New scrap	Old scrap	New scrap	Old scrap	
Crippings.....	4,063		3,974		8,037
Sheet and strip.....		5,584		269	5,853
Engravers' plates.....		2,236		65	2,301
Scumming and ashes.....	39,605		25,297		64,902
Dross.....	48,605		8		48,613
Die castings and other alloyed zinc.....	2,854	8,010	147	69	11,080
Flue dust and residues.....	13,809	14,414	19,086	10,965	58,214
	108,936	30,244	48,512	11,308	199,000

Zinc-base scrap consumption totaled 199,000 tons in 1944, 13,248 tons more than in 1943, the greatest increases being in flue dust and chemical residues whose use rose to 58,214 tons from 47,725 tons in the previous year, and in dross, treatment of which increased to 48,613 tons from 43,894 tons in 1943. Total metallic zinc scrap consumption decreased to 27,271 tons from 29,796 tons in the previous year.

Consumption of zinc residues exhibited a rising trend through the first half of 1944, reaching a peak in July, after which monthly consumption fell for the remainder of the year. Consumption of metallic scrap varied from month to month during 1944, but there was no

definite upward or downward trend. Most metallic zinc scrap was handled by scrap-metal dealers, whereas most of the drosses and residues moved directly from generators to smelters or chemical works. The scrap market for zinc solids was rather inactive owing to lack of labor, shortage of transportation, and in many industrial areas a winter of exceptionally heavy snowfall, which further impeded collection and transportation of scrap.

Shipments of zinc scrap to consumers by nonferrous scrap-metal dealers during 1944 totaled 42,771 tons, a decrease of 1,712 tons from the 1943 total of 44,483 tons and 15 percent below the 1942 figure of 50,435 tons. The monthly total of shipments fluctuated from the low point of 3,051 tons in February to a high of 3,968 tons in June, then to the year's low point of 2,981 tons in December. Dealers' stocks, with slight variations, climbed steadily from 5,344 tons on January 1 to 6,744 tons at the end of the year.

Of the total zinc-base scrap treated, 14 percent was in metallic form, the remainder being drosses and residues, but 69 percent of the zinc recovered from both of these classes of scrap emerged in metal products and only 31 percent in chemical form. One reason for the high percentage of metal products is the facility with which galvanizers' dross, one of the big residue items, can be treated by distillation to yield slab zinc or zinc dust. Another is the practice of some smelters of mixing flue dust with ore in distillation operations.

The amount of zinc drosses and residues made is a function, not of the demand for the residue but of the demand for the products in whose manufacture the residues are generated. Consumption of scrap equals the amount generated plus or minus changes in stocks so that ordinarily, in the secondary zinc industry, high consumption of zinc residues accompanies expanded galvanizing operations, which generate dross, expanded brass-ingot production, which generates zinc oxide flue dust, and expanded sodium hydrosulfite manufacture, which generates zinc-base chemical residues. Studies of the ratio between slab-zinc consumption and zinc-residue consumption have borne out the above conclusion.

Consumers' stocks of purchased zinc-base scrap in the United States at end of year 1943-44, gross weight, in short tons

Scrap item	On hand—	
	Dec. 31, 1943	Dec. 31, 1944
Metallic zinc scrap	3, 574	2, 222
Dross	6, 579	7, 475
Skimmings and residues	27, 485	20, 164
	37, 638	29, 861

The zinc supply situation on the first of the year was such that the War Production Board began relaxing some of the controls on the uses of zinc. Restrictions were modified a dozen times during the year so that the number of items for which zinc could be used without restriction continually increased. On February 22 remelt zinc was removed from allocation, and deliveries of zinc scrap were allowed without restriction. Use of all monthly zinc allocation certificates was discontinued on September 15. However, all these relaxations did not

case much of a rise in the consumption of zinc for civilian purposes; that use was limited by other factors, such as lack of steel for galvanizing.

Ceiling prices for secondary slab zinc remained the same as in 1943, the price for Prime Western zinc being 8.25 cents a pound. Maximum prices for zinc scrap also remained unchanged, with new clippings at 7.25 cents a pound and old zinc at 5.75 cents. Dealers' buying prices for new zinc clippings at New York averaged 5.81 cents per pound during 1944, a slight decrease from the monthly average of 5.88 cents in 1943 and 0.64 cent less than the 1942 figure of 6.45 cents. The year began with this material quoted at 5.62 cents, and the quotation reached 5.87 cents by April, where it remained until the close of the year. Dealers' buying prices for old zinc scrap had a monthly average of 4.31 cents per pound, compared with 4.12 cents in 1943 and 4.65 cents in 1942.

Imports of old zinc scrap into the United States totaled 186 tons in 1944 compared with 114 tons in 1943. Imported drosses and residues totaled 4,694 tons in 1944, a decrease of 338 tons from the 5,032 tons received from abroad in 1943. Large quantities of fume from a primary smelter in Canada were imported by one company for the manufacture of zinc sulfate and lithopone, but the zinc reclaimed from this material was not counted as secondary zinc.

MAXIMUM PRICES FOR CERTAIN SCRAP METALS

COPPER AND BRASS SCRAP

(Set by O. P. A.; effective Jan. 25, 1944)

The following are maximum prices, f. o. b. freight cars, trucks, or other means of transportation at the point of shipment and include all commissions and service charges:

Item No.	Grade of scrap	Maximum price per pound of material (cents)
1.	No. 1 copper wire and No. 1 heavy copper	9.75
1.	No. 1 tinned copper wire and No. 1 tinned heavy copper	9.75
1.	No. 2 copper wire and mixed heavy copper	8.75
1.	Copper tuyeres	8.75
1.	Light copper	7.75
1.	No. 1 copper borings	8.75
1.	No. 2 copper borings	7.75
1.	Lead covered copper wire and cable	(1)
1.	Insulated copper	(1)
2.	Bell metal	15.50
2.	High grade bronze gears	13.25
2.	High grade-low lead bronze solids	(3)
2.	High grade bronze solids	(3)
2.	High grade-low lead bronze borings	(3)
2.	Babbitt lined brass bushings	13.00
2.	High lead bronze solids	(3)
2.	High lead bronze borings	(3)
2.	Red trolley wheels	10.75
2.	Tinny bronze (phosphor bronze) solids	10.50
2.	Tinny bronze (phosphor bronze) borings	10.50
2.	Copper nickel solids and borings	9.25
2.	Bronze paper mills wire cloth	9.50
2.	Aluminum bronze solids	9.00
2.	Soft red brass (No. 1 composition)	9.00
2.	Soft red brass borings (No. 1 composition borings)	9.00
2.	Contaminated gilding metal solids	8.50
2.	Contaminated gilding metal turnings	8.50
2.	Unlined standard red car boxes	8.25
2.	Lined standard red car boxes	7.75
2.	Cocks and faucets	7.75
2.	Mixed brass screens	7.75
2.	Red brass breakage (irony composition)	7.50
2.	Old nickel silver solids	6.25
2.	Old nickel silver borings	6.25
2.	Yellow brass castings	5.25
2.	Copper-lead solids	5.56

See footnotes at end of table.

4.	Refinery brass (over 60% Cu).....	(7)
4.	Refinery brass (50.01% to 60% Cu).....	(8)

¹ (a) Multiply gross weight, less weight of lead covering and any insulation by price for applicable grade of copper wire; (b) divide result by gross weight; and (c) deduct from resulting quotient 0.15¢. This is maximum price. In addition payment may be made for lead covering at maximum price established by MPR 70. Maximum price may be determined by applying foregoing to representative sample.

² (a) Multiply gross weight less weight of insulation by price for applicable grade of copper; (b) divide result by gross weight; and (c) deduct from resulting quotient 0.15¢. This is maximum price. Maximum may be determined by applying foregoing computation to representative sample.

³ Price shall be determined by application of section 16 (a) (3) of MPR 20 to analysis, other than by inspection, of material. If consumer receives less than 5,000 pounds in a shipment, he may determine by inspection that material meets specifications but in such case the maximum is 10.75¢. High grade-low lead bronze solids which, except for the copper content or the tin content, or both, meet the specification and which, except for form, meet the specification for high grade-low lead bronze borings, may be priced as high grade-low lead bronze borings. In either case, price is subject to 1% reduction for each 7% of dirt, etc.

⁴ Price shall be determined by application of Section 16 (a) (3) of MPR 20 to wet or natural analysis after button analysis has determined proper classification. If consumer receives less than 5,000 in a shipment at one time, he may determine by inspection that material meets specification but in such case maximum is 10.00¢ subject to 1% deduction for each 1% of dirt, etc.

⁵ Maximum shall be calculated by application of following method to analysis other than by inspection

1.25% Zn or less: Cu content x 9.25¢ + Sn content x 33¢

1.26% to 4% Zn: Cu content x 9¢ + Sn content x 32¢

4.01% Zn or more: Cu content x 8.5¢ + Sn content x 30¢

However, 0.01¢ per pound of material shall be added or deducted for each 0.01% antimony below 0.25% or above 0.75%. If consumer receives less than 5,000 pounds in a shipment at one time he may determine by inspection that material meets specifications but in such case maximum is 9.50¢. High lead bronze solids which, except for the copper content or the tin content, or both, meet the specification for high lead bronze borings may be priced as high lead bronze borings. In either case, price is subject to 1% deduction for each 1% of dirt, etc.

⁶ Apply same method as for high lead bronze solids to wet or natural analysis after button analysis has determined proper classification of zinc content. If consumer receives less than 5,000 in a shipment at one time, he may determine by inspection that material meets specifications but in such case maximum is 8.5¢ subject to 1% deduction for each 1% of dirt, etc.

⁷ 60.01% dry copper content (61.31% wet assay) times 8.00¢.

⁸ 50.01% dry copper content (51.31% wet assay) times 7.75¢.

QUANTITY PREMIUMS

(i) For shipment at one time of 60,000 pounds or more of only one item other than Item 4—3¢ per pound;

(ii) For shipment at one time of 40,000 pounds or more of one or two items—1½¢ per pound;

(iii) For the shipment by one person in one railroad car of 60,000 pounds or more of material eligible for the 0.75 cent per pound premium provided for in subdivision (i) of this paragraph and, in the same railroad car, 20,000 pounds or more of any one other group—0.50 cent per pound for the material composing such other group in addition to 0.75 cent per pound for the 60,000 pound group.

No quantity premium may be added if any special use, briquetting or crucible shape premium has been added to such price.

BRIQUETTING AND CRUCIBLE SHAPE PREMIUMS

No. 1 copper wire and No. 1 heavy copper..... 14¢

No. 1 tinned copper wire and No. 1 tinned heavy copper..... 14¢

No. 2 copper wire and mixed heavy copper..... 1¢

Copper borings..... 15¢

Manganese bronze solids..... 21¢

All other copper alloy scrap..... 14¢

Above premiums not applicable on sales to copper refiner or brass and bronze ingot manufacturer.

SPECIAL USE PREMIUMS

To the maximum price of any grade of copper scrap a special use premium of 14¢ may be added if the material has been prepared to meet the consumer's specifications and is suitable for direct use without further preparation. Not applicable on sales to refinery, ingot maker, foundry or brass mill.

No special use, briquetting or crucible shape premium may be added if any quantity premium has been added.

BRASS-MILL SCRAP

Revised to Oct. 29, 1942, by O. P. A. (f. o. b. shipping point)

	Heavy Scrap	Rod Ends	Turn- ings
Copper.....	10¼	10¼	9¼
Used copper.....	9¾	9¾	9¾
Commercial bronze:			
90% or more Cu.....	9¼	9¼	8¾
90% to 95% Cu.....	9¾	9¼	8¾
Red brass: 80% or more Cu.....	9¼	8¾	8¾
Best quality brass: 71% to 80% Cu.....	8¾	8¼	8
Y-cow brass.....	8¾	8¾	7¾
Muntz metal.....	8	7¾	7¼
Nickel silver:			
50% Ni.....	9¼	9	4¾
100% Ni.....	10¼	9¾	5¼
15% Ni.....	10¾	10¾	5¼

Maximums are for shipments of less than 15,000 pounds. For 15,000 to 40,000 pounds add 0.62½¢ but heavy scrap may not be mixed with rod ends and/or turnings. For over 40,000 pounds add 1.00¢ for any mixture.

ZINC SCRAP

Established Oct. 17, 1941, by O. P. A. (per lb. f. o. b. point of shipment)

(Prices are for clean, dry scrap, free of iron and other foreign material)

New zinc clippings and trimmings.....	7.25¢
Engravers' and lithographers' plates.....	7.25¢
Old zinc scrap.....	5.75¢
Unsweetened zinc dross.....	5.80¢
Die cast slab.....	5.80¢
New die cast scrap.....	4.95¢
Radiator grilles, old and new.....	4.95¢
Old die cast scrap.....	4.50¢

Premium of 0.50¢ per pound allowed for shipments at one time of 10,000 pounds of new zinc clippings, engravers' and lithographers' plates and old zinc scrap or any combination of the three; and for shipment at one time of 20,000 pounds of new or old die cast scrap and radiator grilles or any combination of the three. No premium is allowed on galvanizers' dross or die-cast slab.

ALUMINUM SCRAP

*Revised to Dec. 23, 1943, by O. P. A. (f. o. b. shipping point)**Following are the maximum prices for aluminum scrap (in cents per pound):*

	I Lots of under 1,000 lb.	II Lots of 1,000 to 30,000 lb.	III Lots of 30,000 lb. or more
1. Plant scrap, segregated:			
Solids:			
All 8-type alloys except 28.....	8½	9½	10
28.....	8	9	9¼
High-grade alloys.....	7	8	8½
Low-grade alloys (Includ. No. 12 and piston alloys).....	6½	7½	8
Borings and turnings:			
High-grade alloys (Includ. all 8-type).....	5½	6½	7
Low-grade alloys (Includ. No. 12 and piston alloys).....	5	6	6½
2. Plant scrap, mixed:			
All solids.....	6	7	7½
Borings and turnings.....	4	5	5½
3. Obsolete scrap:			
Pure cable.....	8	9	9¼
Old sheet and utensils (98% minimum aluminum).....	7	8	8¼
Old castings and forgings.....	6½	7	7¼
Pistons free of struts.....	6½	7	7¼
Pistons with struts.....	4½	5	5¼
Old alloy sheets.....	5½	6	6½
4. Wrecked aircraft (prepared):			
90% plus aluminum alloy content.....			7
70-90% aluminum alloy content.....			6
50-70% aluminum alloy content.....			4
Per pound of aluminum alloy recovered, irrespective of quantity. In the case of wrecked aircraft, and of drosses, skimmings, grindings, sweepings, and spatters, the maximum prices established for such scrap are delivered to the buyers' receiving point.			
5. Drosses, skimmings, grindings, sweepings, sawings, spatters:			
50% plus aluminum.....			5¼
Under 50%.....			4¼

Per pound of aluminum contained, irrespective of quantity, as determined by fire assay or hydrogen evolution. In the case of wrecked aircraft, and of drosses, skimmings, grindings, sweepings, and spatters, the maximum prices established for such scrap are delivered to the buyers' receiving point.

6. Aluminum foil scrap:

Aluminum foil scrap or light gauge aluminum sheet which does not exceed 0.006 of an inch in thickness; clean, free of paper, gutta-percha or any other adhering substances or forms of contamination—16 cents per pound of material, irrespective of quantity. Contaminated aluminum foil scrap not conforming to these specifications shall be bought and sold for not more than a price, below the maximum price for clean aluminum foil scrap, fairly reflecting the value of such scrap.

Note 1. Meaning of terms. "Plant scrap" means scrap generated in the course of fabrication or manufacture and includes new material or parts rejected or discarded because defective, damaged in processing, part of surplus or idle inventory, or otherwise unfit for use. The mean plant scrap generated by shearing, clipping, cutting, blanking, or similar process, also defective or rejected wrought aluminum parts, defective or rejected castings, and gates, sprues, risers, or similar foundry scrap. Scrap shall not be deemed "segregated", whether in the form of solids or in the form of borings, turnings or other machinings, unless it consists of one alloy only and is so identified and handled as to be accepted for reprocessing into aluminum of the original alloy specifications without the necessity for other than routine examination by the processor. The supplier must deliver to the buyer Segregation Certificate PD-706 showing alloy number and specification, and that scrap meets the specification. "Segregation low grade" scrap includes all alloys containing over 1% iron by weight (including free iron) except alloy PM 754. "Segregated S-type alloy solids" consist of scrap generated from the wrought or S-type alloys such as 17S or 24S. All segregated alloy solids which are not low-grade or S-type are "high-grade."

Note 2. Iron, oil, moisture, etc. If borings, turnings, and similar machinings or other grades of aluminum scrap contain oil, water, or other forms of contamination, maximum prices may be paid only on basis of actual weight of aluminum or aluminum alloy contained. If aluminum or aluminum alloy content by weight is less than 85% of weight of material, buyer may only pay delivery charges on that portion of weight of material represented by weight of aluminum or aluminum alloy content.

Note 3. Quantity differentials. The requisite quantities for which premiums are provided in columns II and III, may consist of various grades of aluminum scrap, but other metals may not be included for the purpose of making up such quantities.

In computing the weight necessary to obtain a quantity differential, the actual weight of the material at the point of shipment, as determined by the public carrier, or as certified to and accepted by the public carrier, or as certified by a public weigher, is to be used. If the weight of the material at the point of shipment is not determined by any of the methods herein specified, the actual weight of the material at the buyer's receiving point shall be used.

Note 4.—Revoked.

Note 5. Wrecked aircraft (prepared). Maximum prices are for actual aluminum alloy content of ingot recovered by the buyer's first melt of the entire shipment. By mutual agreement of buyer and seller, 20% of shipment by weight may be used as representative sample in determining amount of aluminum alloy recovered. Where less than 10,000 pounds are received at one time the buyer may estimate the amount of aluminum alloy which will be recovered and make settlement on the basis of that estimate.

Note 6. Premiums for special preparation. (a) Upon the sale of segregated solid aluminum plant scrap of any of the wrought aluminum or S-type alloys, except 2S and 3S, to the Aluminum Company of America, the Olin Corporation, or the Reynolds Metals Company, the following premiums may be charged, demanded, paid, or offered.

	Premium (cents per pound)
Baled or packaged, for briquetting.....	1/4
Briquetted or in large pieces too heavy to briquet.....	1

(b) Upon the sale of wrecked aircraft, prepared, a premium of one-half cent per pound of material may be charged, demanded, paid, or offered if such scrap is baled by compression or briquetted.

(c) The maximum price charged for aluminum scrap specially prepared or processed in any other manner shall be a price hereafter established in writing by the Office of Price Administration. The price so established shall be a price in line with the general level of prices established by this Maximum Price Regulation No. 2, taking into account the buyer's special requirements and the additional cost to the seller in preparing material to meet the buyer's requirements.

IRON AND STEEL SCRAP¹

GENERAL SUMMARY

The demand for iron and steel scrap continued high in 1944. The total consumption was only slightly less than the peak recorded in 1943, as a 1-percent rise in the use of home scrap was offset by a 2.6-percent decline in the consumption of purchased scrap. Because of the shortage of merchant scrap, consumers' stocks were drawn upon heavily, and a 25-percent reduction resulted. There was some increase in inventories of purchaseable scrap, but the net decline in total stocks of all types of scrap was 17 percent.

The slight reduction in iron and steel scrap consumption was accompanied by a small rise in the output of steel ingots and castings. Monthly production of the latter reached an all-time peak in March 1944 and for the first 7 months of the year exceeded the output in the corresponding months of 1943. In the late summer and fall, over-optimism regarding the outlook for termination of the war in Europe was reflected in lower production rates, so that the net increase in steel production for the year was less than 1 percent. Pig-iron production followed a similar pattern, the net gain for the year being 0.3 percent, and the last 5 months of the year showed lower tonnages than the corresponding months of the preceding year.

Consumption of scrap was fairly uniform throughout the year and responded to monthly steel-production rates that varied between the relatively narrow limits of 93 and 99 percent of capacity. The high point of the year was in March, when 5.4 million net tons were consumed. This compares with the previous year's maximum in October of 5.4 million tons and with the all-time high in October 1941 of 5.6 million tons.

The average steel-furnace charge in 1944 did not differ from that in 1943, in each year 47 percent of the ferrous raw materials was scrap and 53 percent was pig iron. There was, however, some change with reference to iron furnaces, which in 1944 used 64 percent of scrap and 36 percent of pig iron as compared with 66 and 34 percent, respectively, in 1943.

¹ Minerals Yearbook, 1939, p. 513, gives definitions of the various scrap terms used in this report.

Of the total scrap used for all purposes in 1944, 59 percent was home and 41 percent purchased, as against 58 and 42 in 1943 and 56 and 44 in 1942. This trend shows clearly the effects of the progressive depletion in recent years of available supplies outside the hands of manufacturers and indicates the increasing difficulties under which the suppliers and dealers have been operating.

Salient statistics of ferrous scrap and pig iron in the United States, 1943-44

	1943	1944	Change in 1944 (percent)
Stocks, December 31:			
Ferrous scrap and pig iron at consumers' plants:	<i>Short tons</i>	<i>Short tons</i>	
Home scrap.....	1,668,103	1,435,056	-14

¹ Includes open-hearth, bessemer, and electric furnaces.

² Includes cupola, air, Brackelsberg, puddling, crucible, and blast furnaces; also direct castings.

³ Includes rerolling, reforging, copper precipitation, nonferrous, and chemical uses.

⁴ Iron Age.

Three important War Production Board scrap regulations were issued in 1944. One had to do with the segregation and use of alloy-steel scrap, the second prescribed the proportion of scrap to be used in steel-furnace charges, and the third permitted the melting of certain grades of low-alloy scrap in heats of carbon steel. The alloy-scrap segregation order was renewed once during the year and withdrawn in the fall, with the warning that if its provisions were not carried out on a voluntary basis the order would be reinstated. The second order ultimately placed the percentages of scrap to be used in open-hearth furnaces at 52 percent and in electric furnaces at 65 percent.

Ceiling prices established in 1941 by the Office of Price Administration for the various grades of scrap continued to set the levels at which scrap changed hands until August 1944, when this price structure yielded to the over-optimism regarding the outlook for termination of the war in Europe. Low points for various grades of scrap were reached in October and November, after which prices rose but not to the ceiling levels. No. 1 Cast, however, remained at ceiling price throughout 1944.

Since Pearl Harbor exports of scrap have been insignificant; imports in 1944 were a minor factor. Comparing 1944 with 1943, exports increased 74 percent but imports declined 22 percent.

A 17-percent decrease in total stocks during 1944 was due to continued high rate of operation in the steel industry and to the depletion of purchasable supplies. The largest decrease was in purchased stocks in the hands of consumers.

Figure 1 shows consumption of purchased scrap and output of pig iron and steel ingots and castings from 1905 to 1944, inclusive.

FIGURE 1.—Consumption of purchased scrap and output of pig iron and steel in the United States, 1905–44. Figures on consumption of purchased scrap for 1905–32 are from *State of Minnesota vs. Oliver Iron Mining Co. et al.*, Exhibits, vol. 5, 1935, p. 328; those for 1933–34 are estimated by authors; and those for 1935–44 are based on Bureau of Mines reports. Data on output of pig iron and steel are as given by the American Iron and Steel Institute.

POSTWAR OUTLOOK

Examination of the data on scrap and pig-iron consumption and steel-ingot and steel-casting production, as reported to the Bureau of Mines for 1937-43, discloses a number of ratios of remarkable uniformity from year to year; these ratios show a maximum deviation from the weighted mean for any year of less than 3 percent. Such an agreement over a period that includes years of recovery, recession, and wartime production offers a basis upon which to predict scrap usage if a satisfactory forecast of postwar steel production rates can be found. Of all such estimates, those furnished to the United States Senate by the Inland Steel Corp. and the U. S. Steel Corp., which are in substantial agreement with those of Walter Tower, seem to be the most acceptable.² These figures place the immediate postwar steel production at 65 to 70 million tons a year.

In addition to the scrap requirements of a 65- to 70-million-ton predicted steel output, allowance must be made for the requirements at iron furnaces. Fortunately the ratio of scrap and pig iron required in iron furnaces has a clearly defined relation to the requirements for steel furnaces, which permits estimation of the total scrap requirements for the entire industry. On this basis it may be expected that steel and iron furnaces (including an estimated steel-casting production not included in the Bureau of Mines published figures) will consume 45 to 49 million short tons of scrap and 44 to 47 million tons of pig iron in the immediate postwar years. It may also be expected that, of the scrap consumed, 54 to 57 percent will be home and 43 to 46 percent purchased scrap.

Since the ratio of scrap (both purchased and home) to ingot production has remained constant over a period of years, it might be expected that if an abrupt drop on the cessation of hostilities from the current annual rate of 90 million tons of ingots to the predicted 65 to 70 million tons occurs, an excess of scrap might be available in the United States that would tend to upset the balance apparent since 1937, especially if ruling prices drop. Several factors will militate against this result. For instance, much finished iron and steel that would ordinarily ultimately find its way into the scrap market when its utility had ceased has been physically destroyed and will never return to industry. Some war-purpose plants undoubtedly will be scrapped, but it is possible and even probable that many war plants and much equipment either will be held in stand-by condition or reconditioned for peacetime use. In addition, accumulations of old scrap, which normally find their way into the market from time to time, have been almost entirely cleared up in the various scrap drives. It is, therefore, even possible that the immediate postwar period will face a short supply of scrap.

PRICES

The average quoted price of Heavy-Melting steel, hydraulic compressed and bundled sheet at Pittsburgh was maintained at \$20 per gross ton (\$17.86 per short ton) between April 1941 and August 1944, then declined to a low of \$16.02 (\$14.31) in October and re-

² War Plant Disposal—Progress Report on the Preparation of Joint Hearings on the Disposal of Surplus Iron and Steel Plants and Facilities to be Held by the War Contracts Subcommittee and the Committee on Military Affairs of the U. S. Senate—April 23, 1946, pp. 6-7; and Walter Tower, President, American Iron and Steel Institute.

tered to \$19.89 (\$17.76) by December.³ The price for No. 1 Cast at \$21.29 (\$19.01) all year. Price for No. 2 Melting dropped from the January–August level of \$20 (\$17.86) to \$14.25 (\$12.72) in October, and recovered to \$19.53 (\$17.44) in December. Machine-shop turnings held uniformly at \$15 (\$13.39) until September, when the price began dropping, and reached a low of \$9.25 (\$8.26) in October; it recovered at \$12.91 (\$11.53) in December. Low-phos railroad specialties held until the end of August at \$23.23 (\$20.74), dropped as low as \$22.25 (\$19.87) in September and October, and then recovered to \$24.16 (\$21.57). The above prices are all Pittsburgh base.

A comparison of the quoted prices for Heavy-Melting scrap at Pittsburgh during the two war periods illustrates clearly how the "hold the line" order has prevented a run-away market in scrap. If for the First World War period the 1914 average is taken as 100 percent, the average yearly prices increased to 116 percent in 1915, 161 percent in 1916, 255 percent in 1917, and 252 percent in 1918. Similarly, considering the average 1939 prices as 100 percent, the average prices were 112 percent in 1940, 118 percent in 1941, 116 percent in 1942, 116 percent in 1943, and 112 percent in 1944.⁴

The price of basic pig iron (as quoted by Iron Age) at Valley furnaces remained at \$23.50 a long ton (\$20.98 a net ton) throughout the year and has been consistently at this level since December 1943.

WAR PRODUCTION BOARD ACTIONS DURING 1944

On January 13 the War Production Board issued Supplementary Order M-24-c permitting the melting of certain grades of low-alloy scrap in the production of carbon steel or iron and defined low-alloy steel scrap so used as (1) Cr or Cr-V scrap containing less than 1.65 percent Cr, (2) Cr-Mo scrap containing less than 0.27 percent Mo, and (3) Ni-Cr-Mo scrap containing less than 0.70 percent Ni, 0.60 percent Cr, and 0.30 percent Mo. The mixing of segregated scrap not falling within the scope of this order (except in the melting of steel) with other grades of scrap was prohibited. The requirement for the segregation of alloy-steel scrap was continued except that producers in quantities below certain fixed limits were excused.⁴ The trade did not expect that the use of these grades of alloy-containing steel scrap would be universally practicable and, in fact, it would not be possible where carbon steel must be alloy-free, or where it is manufactured to rigid specifications. This Board action was taken to relieve the shortage of carbon-steel scrap.

On September 7, 1944, Supplementary Order M-24-c was reissued, using exactly the same wording as the issue of January 13,⁵ because the order of January 13 had expired by limitation.

On October 26 the supplementary order was revoked.⁶ It was pointed out that revocation of this order and of Direction 4 to Order M-21-a (see below), which was revoked on the same date, did not mean that proper segregation of scrap and use of alloy scrap could be discontinued, and if these usages were not carried out on a voluntary basis controls would be reinstated.

On January 21, 1944, the Board issued⁷ a Direction under Supple-

³ American Metal Market, vol. 52, No. 1, January 3, 1945, p. 9.

⁴ Federal Register, vol. 9, No. 10, January 14, 1944, p. 571.

⁵ Federal Register, vol. 9, No. 179, September 7, 1945, p. 10980.

⁶ Federal Register, vol. 9, No. 215, October 27, 1945, p. 12865.

mentary Order M-21—a prescribing the use of 60-percent alloy scrap in the melting of alloy steel in electric-furnace charges and 50 percent in open-hearth charges, of which a minimum of 8 percent had to be turnings, including machine-shop turnings.⁷ It had been found⁸ that before this order the use of alloy scrap in melting alloy steel varied between 29 and 59 percent of the charge. The direction was for the purpose of relieving the demand for carbon scrap which was depleting stocks at an alarming rate. Some doubt was expressed as to the practicability of the order. In the light of a later direction, these fears seem to have been unfounded, since on September 13 Direction 4 to Order M-21-a was issued,⁹ increasing the percentage of alloy scrap to be used in electric furnaces to 65 percent and that in open hearths to 52 percent. Tungsten steels, stainless steels, and certain high-alloy heat-resisting steels were excluded from both directions. The Steel Industry Advisory Committee recommended that Direction 4 be kept in force to conserve alloys and reduce the contamination in carbon steel.

On October 26, Direction 4 was revoked (see comment above).¹⁰

In June 1943 the Board had prohibited the scrapping of serviceable automotive parts. This resulted in wreckers holding cars containing serviceable parts in their yards without immediate dismantling.

An amendment to Order M-311 clarified the original order and, in addition, permitted the scrapping of certain parts, so that cars could be dismantled and find their way quickly into the scrap market.

Other Board Action.—During the year various conferences, press releases, and similar publicity action were initiated by the War Production Board to keep the flow of scrap at the maximum level.

OFFICE OF PRICE ADMINISTRATION ACTIONS DURING 1944

On January 11 the Office of Price Administration issued Supplementary Order 82, effective January 13.¹¹ This supplementary order has the effect of relieving the War Department, the Navy Department, and Procurement Division of the Treasury from price-control regulations when selling scrap or waste metals to a dealer who in his turn will certify that the materials are for resale at not above OPA ceiling prices. The order also relieves Government agencies and their employees from civil or criminal liability resulting from the sale and delivery of materials under this supplementary order.

Amendment 14 to Revised Price Schedule 4, became effective February 19, 1944. This amendment established specific dollars-and-cents differentials to be applied to the maximum price of No. 1 Railroad Heavy-Melting steel scrap by railroads, car-manufacturing companies, and switching companies, which determined the ceilings for 35 grades of railroad-steel scrap. At the same time, specific maximum prices for seven listed grades of cast-iron scrap sold by railroads were announced. An increase from \$2:50 to \$3.50 per gross ton, or a specific increase of \$1 per gross ton, was allowed in the dealers' fee for preparing heavy breakable cast iron scrap into foun-

dry sizes. On May 2 a further amendment to Revised Price Schedule 4 was announced by the OPA. This amendment had in part to do with the clarification of weights to govern rail shipments, vessel shipments, and imports of scrap.¹² Amendment 1 to MPR 4 effective November 16, 1944,¹³ authorized the addition of "established shipping charges" to the legal price for the point of shipment to the point of delivery to establish maximum delivered prices.

ALLOY-STEEL SCRAP

Throughout the year a marked tendency of purchasers to refuse alloy scrap was noted although clean carbon steel and iron scrap were in demand. One of the most extreme expressions of this sentiment was:¹⁴

It is reported that one large scrap user * * * has been a buyer of nickel turnings * * * at a reported price of \$5 per gross ton f. o. b. producer plant. These turnings, at the height of wartime demand, sold at better than \$19 f. o. b. shipping points.

During the year alloy scrap frequently was sold at far below ceiling prices, and alloy turnings and borings were particularly difficult to dispose of. In March it was reported in trade papers that of the approximately 2,000,000 gross tons of total scrap consumed, only about 100,000 tons were alloy. Since the alloy-steel production accounted for somewhat over 10 percent of the total steel produced, it can be seen how far this alloy-scrap consumption was out of line.

However, the large alloy-steel producers seem to be willing to purchase properly segregated scrap of their own manufacture and probably other brands of guaranteed analysis, particularly from steel consumers who have set up reliable mechanism for the proper segregation of scrap produced. This emphasizes further the necessity for continued segregation of scrap of known analysis mentioned in the paragraph on WPB actions above.

Unless this course is adopted and until simple methods of identification are worked out, it appears that a large volume of unsalable alloy scrap will accumulate and burden the scrap market for a long time to come. In view of the frantic efforts to obtain a sufficient supply of alloying elements in the early war years, it seems evident that methods should be developed to utilize the alloy content of the scrap.

Battlefield scrap.—During 1944 the War Department sold 142,162 long tons of overseas scrap at an average price of \$9.93 per ton in the United States. Since this material unquestionably contained little or no turnings, borings, or similar materials, the low price can be attributed in part to reluctance of the bidders to pay anything like ceiling prices for the material, much of which is heavily alloyed.

As a comparison, material offered by the Army at Medford, Mass.,¹⁵

¹² Federal Register, vol. 9, No. 87, May 2, 1944, p. 4599.

¹³ Federal Register, vol. 9, No. 227, November 14, 1944, pp. 13583-4.

¹⁴ American Metal Market, Pittsburgh Scrap Prices Reflect Firmer Tone: Vol. 51, No. 203, October 19, 1944, pp. 1-8.

¹⁵ American Metal Market, Additional Scrap Allotment Sought for New England: Vol. 51, No. 159, August 16, 1944, p. 7.

"auto scrap or truck scrap of one kind and another plus some structural scrap" was bought for \$10.37 a gross ton for heavy material, whereas only \$6 to \$8 was offered for tank scrap. Some users are reported to have refused to take any tank scrap. The problem of the ultimate disposal of the large quantities of heavily alloyed battlefield scrap only accentuates the general problem of the use of alloy scrap.

It is understood that the Army is concentrating on returning carbon scrap to this country and stocking alloy scrap in Europe.

STOCKS

On December 31, 1944, the supply of ferrous scrap in the hands of consumers, suppliers, and producers totaled 5,969,217 short tons, a 17-percent decline from the 7,175,500 tons on hand on December 31, 1943. This is the second year in succession when a loss in total stocks was experienced, the decline in 1943 being 7 percent.

The largest loss (over 1,000,000 short tons) was in purchased scrap in the hands of consumers. The magnitude of the demand for scrap is best illustrated by the fact that 25,900,000 tons of purchased scrap were consumed during the year. It is greatly to the credit of the scrap dealers that they could keep a steady stream of scrap flowing into the hands of consumers. No serious shut-down during the year for lack of scrap has been reported. Credit must also be given the consumers for arranging their operations in such manner as to keep a continuing supply of steel while facing such a marked decline in the immediately available supply of scrap.

CONSUMERS' STOCKS

Consumers' total home and purchased stocks on December 31, 1944, had decreased to 4,418,719 net tons or 25 percent from 5,872,251 tons at the beginning of the year. Stocks of home scrap (1,435,056 tons), had decreased by 14 percent and of purchased scrap (2,983,663 tons), by 29 percent.

Stocks of pig iron on December 31, 1944, amounted to 1,501,599 short tons, an 8-percent decrease from the 1,634,701 tons on hand on January 1.

These decreases of stocks in consumers' hands resulted from the continued high rate of steel and iron production. On the whole, the scrap industry in 1944 was able to supply the continued high demands to such good advantage that the stocks in consumers' hands were not too seriously depleted.

SUPPLIERS' AND PRODUCERS' STOCKS

Stocks in the hands of dealers, automobile wreckers, railroads, and manufacturers increased from 1,303,249 net tons on December 31, 1943, to 1,550,498 tons on December 31, 1944—a gain of 19 percent. This represents the largest year-end accumulation in the hands of suppliers since the close of 1940. Stocks held by dealers, railroads, and manufacturers increased by 26 percent, whereas the stocks of automobile wreckers decreased by 58 percent.

Consumers' stocks of ferrous scrap and pig iron on hand in the United States on Dec. 31, 1943, and Dec. 31, 1944, by States and districts, in short tons

CONSUMPTION

In gathering data on the consumption of scrap in 1944, the practice of the 2 previous years was continued, in that figures on the use of scrap in the production of ferro-alloys and for various miscellaneous uses are included.¹⁶ Figures for some States are grouped to avoid disclosing the details of individual operations.

The large use of scrap as compared with that of pig iron again was noticeable in the New England, Southwestern, and Pacific Coast districts in 1944.¹⁷ These districts used 6 percent of the scrap consumed in the United States but only 2 percent of the pig iron. The ratio of scrap to pig iron in these three districts was 3.08:1, whereas for the United States at large it was 1.01:1.

Open-hearth steel furnaces are by far the largest consumers of ferrous scrap and pig iron. The portions of the total scrap and pig iron supply used in open-hearth furnaces have remained relatively constant as the following data will show: Open-hearth consumption accounted for 67 percent of the total scrap and in 1944, 65 percent in 1943, and 66 percent in 1942; 73 percent of the home scrap in 1944, 73 percent in 1943, and 71 percent in 1942; 57 percent of the purchased scrap in 1944, 55 percent in 1943, and 59 percent in 1942; and 79 percent of the pig iron in 1944, 78 percent in 1943, and 77 percent in 1942.

A slight downward trend in cupola-furnace consumption is to be noted: Home scrap, 10 percent of the total in 1944, 10 in 1943, and 12 in 1942; purchased scrap, 15 percent in 1944, 17 in 1943, and 19 in 1942; pig iron, 6 percent in 1944, 6 in 1943, and 8 in 1942. Taken together open-hearth and cupola furnaces in 1944 used 79 percent of the total scrap and 86 percent of the pig iron consumed.

Bessemer converters consumed 9 percent of the pig iron in 1944 (10 percent in 1943) but only about 0.6 percent of the scrap.

Electric furnaces consumed 10 percent of the total scrap in 1944 (11 percent in 1943) but only about 0.4 percent of the pig iron.

Ferrous scrap and pig iron consumed in the United States and percent of total derived from home scrap, purchased scrap, and pig iron, 1943-44, by districts

¹ Includes some pig iron used in making direct castings.

² Where 2 or more separate departments, such as blast-furnace, open-hearth, foundry, etc., are situated at the same place and are operated by 1 establishment, each appears as 1 plant in the total.

CONSUMPTION BY DISTRICTS AND STATES

As might be expected, the condition noted in the last six chapters on Iron and Steel Scrap in Minerals Yearbook prevailed during 1944 in that all 48 States, the District of Columbia, and Alaska were consumers of ferrous scrap and pig iron; and that the largest consuming districts were the North Central, Middle Atlantic, and Southeastern. Consumption in the Southwestern district has decreased markedly

from the 1942 and 1943 levels. The 8 States having the largest consumption of scrap, together with the percentage consumed, were: Pennsylvania 30, Ohio 20, Indiana 12, Illinois 8, Alabama 5, New York 5, Maryland 4, and Michigan 3. The above order is slightly at variance with that noted in 1943; Alabama and New York have changed positions, as have Maryland and Michigan.

Consumption of ferrous scrap and pig iron in the United States in 1940-44, by districts

¹ Less than 0.05 percent.

² Where 2 or more separate departments, such as blast-furnace, open-hearth, foundry, etc., are situated at the same place and are operated by 1 establishment, each appears as 1 plant in the total.

CONSUMPTION BY TYPE OF FURNACE

Open-hearth furnaces.—Ferrous scrap and pig iron consumed in open-hearth furnaces in 1944 totaled 89,089,225 short tons, a 2-percent increase over 1943. The use of home scrap increased 2 percent, of purchased scrap 1 percent, of total scrap $1\frac{1}{2}$ percent, and of pig iron 2 percent.

Charges to open-hearth furnaces in 1944 consisted of 46 percent total scrap and 54 percent pig iron, the proportions being the same as in 1942 and 1943. Of the total scrap consumed, 36 percent was purchased compared with 37 percent in 1943, 41 percent in 1942, and 40 percent in 1941.

Pennsylvania led in the use of scrap in the open-hearth in 1944, followed in order by Ohio, Indiana, and Illinois, which ranking is unchanged from 1943.

Bessemer converters.—The total of 5,969,623 short tons of ferrous raw materials used in bessemer converters in 1944 represents a 10-percent decrease from the 1943 use of these materials. The proportion of scrap in the metal charges was 7 percent, of which 71 percent was home scrap.

Following the pattern of the three previous years, Pennsylvania was the principal consumer of scrap in converters in 1944.

Electric steel furnaces.—Ferrous scrap and pig iron used in electric furnaces in 1944 amounted to 6,662,336 short tons, a decrease of nearly 9 percent from the record consumption of 7,308,240 tons in 1943. The recent high consumption of ferrous raw materials in electric-furnace practice is a direct reflection of the tremendous increase in the number of these furnaces, which amounts to "a 287.5 percent increase in electric furnace capacity."¹⁸

The decrease of 153,339 short tons of pig iron consumed in 1943 from the 1942 consumption is in large part due to a decrease of 138,469 tons in Ohio, which is a reflection of changes in melting practice.

¹⁸ War Plants Disposal, Iron and Steel Plants, Second Progress Report on the Preparation of Joint Hearings on the Disposal of Surplus Iron and Steel Plants and Facilities to be held by the War Contracts Subcommittee of the Committee on Military Affairs and the Industrial Reorganization Subcommittee of the Special Committee on Postwar Economic Policy and Planning, June 14, 1945, p. 16.

Cupola furnaces.—In 1944 cupola furnaces used 11,487,151 short tons of scrap and pig iron, a decrease of 1 percent from 1943. The use of home scrap increased 1 percent, purchased scrap decreased 13 percent, total scrap decreased 6 percent, and pig iron increased 9 percent. The decrease in purchased scrap and the increase in pig iron were due to the marked shortage of good cast scrap and the availability of pig iron for cupola use.

Charges to cupola furnaces consisted of 32 percent home scrap, 34 percent purchased scrap, and 34 percent pig iron, compared to 31, 38, and 31 percent, respectively, in 1943.

The relative position of the principal scrap-consuming States changed slightly from 1943 in that Wisconsin exceeded New York in 1944. Michigan used the largest tonnage, followed in order by Ohio, Illinois, Pennsylvania, Wisconsin, and New York.

Includes some pig iron used in making direct castings.

Air furnaces.—Scrap and pig iron consumed in air furnaces in 1944 amounted to 1,690,343 short tons, a 4-percent decrease from the 1,767,330 tons melted in this type of furnace in 1943. The use of home scrap decreased 6, purchased scrap 4, and pig iron 7 percent.

There was no change in the relative position of the principal consuming States. As in 1942 and 1943, Ohio led in the use of scrap in air furnaces, followed in order by Illinois, Pennsylvania, Indiana, Michigan, Wisconsin, and New York.

¹ Includes 2 Brackelsberg furnaces, 1 each in Indiana and Ohio.

Crucible and puddling furnaces.—Crucible and puddling furnaces consumed only minor amounts of ferrous raw materials. The consumption in these furnaces reached a high point of slightly over 30,000 short tons a year in 1941 and 1942, dropped to 19,562 tons in 1943, and experienced a further decrease to 11,922 tons in 1944.

Blast furnaces.—Materials other than scrap constitute by far the largest proportion of the blast-furnace charge and in 1944 were 94,129,085 net tons of iron and manganiferous ores, 18,946,302 tons of sinter, cinder, and mill scale, 3,518,855 tons of open-hearth and bessemer slag, 129,166 tons of raw flue dust, and 49,901 tons of miscellaneous materials.

Total consumption of scrap in 1944, as reported by 78 plants operating blast furnaces, was 3,638,460 net tons, a 2-percent increase over 1943. These figures do not include 11,710 tons of home and 29,100 tons of purchased scrap used in blast furnaces in the manufacture of ferro-alloys. The scrap charged to blast furnaces was divided into 39 percent home and 61 percent purchased as against 40 and 60 percent, respectively, in 1943 and 53 and 47 percent in 1942. The ratio of home to purchased scrap used in blast furnaces in 1944 is a continuation of the trend previously noted.¹⁰ The ratio of scrap used to pig iron produced is 5.96 percent as it was in 1943; purchased scrap accounted for 3.63 percent and home scrap 2.33 percent.

¹ Does not include scrap used in blast furnaces for the production of ferro-alloys.

¹⁰ Minerals Yearbook, 1943 p. 545.

USE OF SCRAP IN FERRO-ALLOY PRODUCTION

The production of ferro-alloys in 1944 consumed 331,032 short tons of scrap, a 12-percent decrease from the 1943 figure. Purchased scrap accounted for 94 percent of the amount used, and home scrap 6 percent. Twenty-nine plants were engaged in this business, the same number as in 1943.

Of the scrap consumed in the manufacture of ferro-alloys, 12 percent was used in blast furnaces, 88 in electric furnaces, and 0.1 percent in the aluminothermic process.

Of a total of 27 plants producing ferro-alloys, 5 operated blast furnaces, 21 electric furnaces and 2 aluminothermic. The apparent discrepancy in the total count is due to the fact that at 1 plant both electric furnaces and the aluminothermic process were employed.

MISCELLANEOUS USES

Slightly less than 2 percent of the 1944 consumption of scrap was for miscellaneous purposes, such as rerolling, in nonferrous metallurgy, and as a chemical agent. The amount so used—1,017,402 short tons—was an increase of 8 percent over the quantity used for these purposes in 1943. Of the amount used, 93 percent was purchased and 7 percent home scrap.

FOREIGN TRADE²⁰

Imports.—Imports of iron and steel scrap in 1944 decreased 22 percent in volume (111,974 short tons as compared with 143,387 tons in 1943) and 18 percent in value (\$1,627,117 as compared to \$1,986,560 in 1943). Of the 1944 imports, 69,049 tons came from Canada, 14,862 from the Canal Zone, 11,533 from Cuba, 11,414 from Trinidad and Tobago, and the remainder in much smaller tonnages from other countries. In addition 19,402 tons of tin plate scrap were imported (16,192 tons from Canada) as compared with 21,927 tons in 1943 and 26,972 tons in 1942.

Exports.—Exports of ferrous scrap from the United States in 1944 were 95,419 short tons valued at \$1,894,980, an increase of 74 percent in tonnage and 77 percent in value over the figures for 1943. Exports were exceeded by imports by 16,555 short tons (not counting 19,402 tons of imported tin-plate scrap). In spite of the considerable increase in exports over 1943, the tonnage exported amounts to slightly less than 3 percent of the 5-year prewar average (for 1935-39) of 3,298,326 tons a year. The high requirement for scrap in this country was the major factor that resulted in this low volume of exports. The 1944 exports included 4,966 tons of tin-plate scrap, circles, strips, cobbles, and waste, and terne-plate clippings and scrap valued at \$431,725. The same materials in 1943 amounted to 1,949 tons valued at \$188,640. The accompanying table shows the principal countries to which scrap was exported during the period 1940-44.

WORLD ASPECTS

Data on world production of iron and steel scrap in 1944 are not available, a continuation of the condition that prevailed in 1943.²¹

REVIEW BY COUNTRIES

Algeria.²²—The Algerian Group for Importation and Purchase of Scrap Iron has been reorganized. The objects of the group are all commercial, financial, and industrial operations relative to the purchase, sale, importation, exportation, requisition, collection, recuperation, storage, handling, transportation, and use of ferro-alloys, of new

²⁰ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

²¹ Minerals Yearbook, 1943, p. 549.

²² Daily Metal Reporter, Reorganize Algerian Scrap-Iron Import Group: Vol. 44, No. 205, October 21, 1944, p. 8.

castings and of all kinds of scrap iron, cast iron or steel needed for manufacturers of the national defense, of public services, of industry and of commerce.

*Argentina.*²³—Bids have been opened recently for the construction of a rolling mill with a maximum annual capacity of from 300,000 to 350,000 metric tons of blooms, which will be operated by a joint Government-private company. Other phases of the program involve the exploitation of iron-ore deposits now being operated on a small scale. It is obvious that the expanding of this industry means a larger consumption of scrap iron and steel in Argentina.

*Brazil.*²⁴—The Brazilian steel industry has set up a new milestone with the production of 45-pound steel rails for domestic use, and the production of rails in excess of 65 pounds will depend upon the completion of the new Volta Redonda steel plant. This plant expects to begin operation late in 1945. At the present time, the Brazilian steel industry supplies about 35 percent of domestic need, but it will have almost double that capacity when the Volta Redonda plant is completed.

Canada.—The 1944 production of steel ingots and castings mounted to 3,024,410 short tons, an increase of 1 percent over the previous year's output but 3 percent below the record of 3,121,000 tons set in 1942. In producing this steel, 1,511,518 tons of pig iron and 1,849,944 tons of scrap were used, the resulting ratio being 45 percent pig iron to 55 percent scrap. Compared with the percentage of scrap used in the 2 previous years (53 percent in 1942 and 54 percent in 1943), a slight tendency toward the use of more scrap and less pig iron is indicated. In 1944 scrap consumption consisted of 54 percent home and 46 percent purchased scrap, a substantial continuation of the previous year's practice.²⁵

Pig-iron production in 1944 increased 5 percent to 1,852,628 short tons from the 1943 production of 1,758,265 tons but was 6 percent lower than the record figure of 1,975,000 tons in 1942. In 1944, 101,454 tons of scrap iron and steel were used in the manufacture of pig iron. Of the 14 Canadian blast furnaces 8 were in blast.²⁶ In September, the War demand eased materially, and in the latter part of the month restrictions on certain civilian items were lifted. Further dropping off of war orders was noticed during October, and in the latter part of the month more orders for civilian use were placed. The rate of steel production during the year was generally above 80 percent and at times considerably higher. The rate of pig-iron production was estimated to be between 58 and 80 percent at different times during the year.

The scrap iron and steel situation seems to follow the usual pattern in that the severe winters effect materially collections of scrap which normally goes into the hands of the dealers. During the early months of the year, steel scrap was none too abundant, but during the late spring, summer, and fall months the supply situation improved so that the dealers and consumers were enabled to build up stocks that were

²³ Daily Metal Reporter, Argentina Plans to Develop Iron and Steel Industries: Vol. 44, No. 188, September 27, 1944, p. 11.

²⁴ American Metal Market, Brazilian Steel Industry Producing 45-pound Rails: Vol. 51, No. 26, February 5, 1944, p. 8.

²⁵ Department of Trade and Commerce, Dominion Bureau of Statistics, Monthly Report—Production of Iron and Steel in Canada, December 1944: Ottawa, Canada, pp. 1-3.

²⁶ Department of Trade and Commerce, Dominion Bureau of Statistics, Monthly Report—Production of Iron and Steel in Canada, December 1944: Ottawa, Canada, pp. 1-3.

deemed ample to satisfy all probable demands through the winter. On the other hand, cast scrap either was in balance with or below actual demands throughout the year.

No. 1 Heavy Melting was in good demand through the entire year, as were the other more acceptable grades of steel scrap. The less-desirable grades appear never to have been in short supply, and purchases were selective in the matter of borings, turnings, and alloy scrap. However, until the late summer or early fall practically all purchases appeared to have been made on ceiling prices. Early in the fall, however, prices as much as \$1.00 below ceiling prices were rumored, although no actual sales were reported. On December 1²⁷ prices were officially revised downward. In spite of the revision (from \$1.00 to \$2.50 a gross ton) particularly active buying did not develop.

The improved collection of scrap during the spring, summer, and fall months, noted above, resulted in great part from the scrap drives, particularly through the rural section. During the same months, considerable scrap was received from the mining districts, and relatively large shipments of this kind of scrap were made from the western part of the Dominion. There have been several press notices during the year to the effect that no battlefield scrap has reached the Canadian market. It is not definitely known whether this situation prevailed during the entire year, but no positive notices of receipts were noted.

Chile.—A plan to meet half of Chile's steel requirements by the construction of a new plant has been announced by Eugene S. Harri-man, consulting engineer of the Chilean Production Development Corp.²⁸ Actual operation of the plant, which is to have an annual capacity of 100,000 tons of finished steel, is to start in the summer of 1946. The expanding Chilean steel industry undoubtedly will offer a market for South American scrap. Chile exported iron and steel products in 1944.

*Luxembourg.*²⁹—Joseph Bech, Luxembourg's foreign minister, has stated that Luxembourg, freed from German occupation only 6 weeks, is now supplying 50,000 tons of steel and 75,000 tons of iron monthly to the United Nations. He also predicted that these amounts would be doubled within a few months. No information is available as to the source of raw material, but it is a fair assumption that battlefield and other wartime scrap, which should now be available in Europe in large quantities, forms an important part of the materials being melted.

SUMMARY

Production of iron ore in 1944 decreased 7 percent from 1943 as a result of a program to reduce considerably the stock of iron ore at plants using Lake Superior ores. Consumption in 1944 was virtually unchanged from 1943. The supply of ore was generally adequate in all consuming districts during the year. However, at year's end a critical supply situation resulting from a labor shortage existed in Alabama and threatened steel output unless an estimated 1,000 men were secured early in 1945. Ten percent of the iron ore used in Alabama in 1944 was from stock. In addition to losses of men to the armed forces, a crusher failure at the Spaulding mine caused a further reduction in ore output.

Manpower shortages in the Northeastern States prevented any important increase in production in that area despite increases in production capacity.

Western production was increased by the opening of four new mines during the year. The Lone Star Steel Co. shipped high-grade ore mined from the greensand beds of east Texas. This ore was shipped to blast furnaces in Illinois and steel furnaces in the Birmingham district. The Sheffield Steel Co. shipped ore from two mines in east Texas to blast furnaces in Illinois and steel furnaces in Houston. A large mine in southwestern Utah was opened in 1944 to ship low-sulfur ore to the Fontana, Calif., furnace.

Of interest to United States consumers of iron ore was the opening of the new Steep Rock mine on the Atikokan range of western Ontario. A considerable shipment of ore from this mine is expected in 1945; it probably will be shipped to United States furnaces.

Price regulations.—The prices announced by the Lake Superior Iron Ore Association for Lake Superior iron ores April 17, 1940, were still in effect at the close of 1944, having been established by the Office or Price Administration, April 10, 1942, as ceiling prices. However, actual selling prices, which had averaged a few cents under the announced prices, were permitted to increase to the ceiling prices, in order to meet additional production costs.

FIGURE 1.—Trends in production of iron ore in the United States, 1880-1944.

POSTWAR OUTLOOK

The long-term future of domestic iron ore depends largely on the feasibility of using the large reserves of low-grade Minnesota taconite. Technology has advanced to a point where 5 to 10 billion tons of high-grade concentrates could be made available from magnetic taconite with present methods. An additional 50 billion tons of non-magnetic taconite await further advancement in concentrating methods. The project initiated in 1943 at Battelle Memorial Institute, Columbus, Ohio, by 12 Lake Superior operators is continuing, and considerable advancement in this field is expected. It is apparent that Lake Superior operators are planning to use these vast reserves when it becomes necessary by reason of the approaching exhaustion of high-grade direct-shipping Mesabi ores.

Meanwhile, ample supplies of domestic ores are usable under present conditions to last a considerable time. Ernest F. Burchard of the Geological Survey and Albin C. Johnson of the Bureau of Mines recently have estimated the present reserves of commercial or usable grade iron ore at 5,478,000,000 gross tons, of which about one-third is classed as inferred ore.¹ Of this ore, 33 percent is situated in the Lake Superior district, 39 percent in the Southeastern district, 7 percent in the Northeastern district, and the Western and Central and Gulf States contain 7 and 4 percent, respectively.

The demand for iron ore in the immediate postwar years may be expected to be substantially below that during the war years. It

¹ Pehrson, Elmer W., *The Mineral Position of the United States and the Outlook of the Future: Min. and Met.*, vol. 28, No. 460, April 1945, p. 208.

seems reasonable to assume an annual steel production of 60 million net tons and a pig iron production of 40 million net tons during the 5 years following Japan's capitulation; thus, requirements for iron ore will average 70 million net tons (60 million gross tons), compared with approximately 100 million net tons in 1943 and 1944. This estimate is based on the fact that the ratio of usable iron ore (direct shipping ore plus beneficiation product) production to pig iron output has averaged 1.72:1 during the last 10 years. No important deviation from this ratio is likely during the immediate postwar years. However, the ratio of crude ore (ore as mined) to usable ore will increase with the gradual exhaustion of high-grade direct shipping ore and greater dependence on ore requiring beneficiation.

Foreign countries are expected to resume supplying a part of United States requirements as soon as shipping is available, but no significant increases above that furnished in the prewar years is expected.

PRODUCTION AND SHIPMENTS

United States iron-ore mines produced crude ore totaling 111,020,145 gross tons and shipped 112,073,286 tons in 1944—decreases of 6 and 7 percent, respectively, from 1943. Of the 1944 shipments 34 percent was sent to beneficiation plants, and 66 percent went direct to consumers, as in 1943. From the crude ore shipped to beneficiation plants, 16,648,364 tons of concentrate and 3,616,297 tons of sinter were produced. In addition, 592,908 tons of byproduct cinder and sinter were produced from the pyrites industry. In all, 94,117,705 gross tons of usable iron ore were produced at mines and mills in 1944. Output came from 224 mines, of which 26 mined over 1,000,000 tons of crude ore each. Minnesota, with 64,878,095 tons, supplied 69 percent of the usable ore; and Michigan, with 12,826,240 tons or 14 percent, was the second-largest producer. These two States and Wisconsin, with 1,406,985 tons or 1 percent, constitute the Lake Superior region, which supplied 84 percent of the domestic output. About three-fourths of the iron ore mined in 1944 came from open-pit mines

Shipments of usable ore from mines totaled 94,544,635 gross tons in 1944. Of this quantity, 74,241,213 tons (79 percent) were direct shipping ore for all uses. Total shipments also include 5,906 tons for cement manufacture, 9,779 tons for paint, and 234,496 tons for miscellaneous uses. Shipments of byproduct ore for iron and steel use totaled 591,040 tons in 1944 valued at \$2,906,656.

In this discussion, the size of a mine is determined by the quantity of crude ore excavated. Consequently, mines providing low-grade ores, which require concentration, will be comparable in size to mines producing similar quantities of direct shipping ores. Twenty-six mines, each yielding more than 1,000,000 gross tons of crude ore, produced 55 percent of the United States output in 1944. Of these producers, 18 were in Minnesota, 3 in Alabama, 2 in New York, and 1 each in Utah, Wisconsin and Pennsylvania; 17 were open-pit operations, 5 underground, and 4 combination mines. Except for 4 mines that produced magnetite, all the million-ton mines produced hematite.

* Excludes an undetermined number of small pits. The output of these pits is included in the total given.

BENEFICIATION

Iron ore is concentrated by washing, jigging, and magnetic and high-density separation to remove objectionable impurities, thereby improving its grade. Fine ores are agglomerated or sintered into lumps, which are desirable in blast and steel furnaces because of their porous character and their improved grade and structure. Sintering likewise has a beneficial effect by reducing the sulfur and moisture content. At many mines the ore is crushed and screened to improve its physical characteristics, but ore known to be so improved is not included in the statistics on beneficiated ore.

In 1944, 20,264,661 gross tons of beneficiated ore were produced from 37,832,073 tons of crude ore. Beneficiation of iron ore was reported at 104 mines in 9 States in 1944 compared with 132 mines in as many States in 1943. Beneficiated ore shipped from domestic mine plants in 1944 decreased less than 1 percent from 1943 and totaled 20,303,422 tons; concentrates comprised 18 percent and sinter 4 percent of total usable ore shipments.

The production of beneficiated ore, concentrates, and sinter in 1944 decreased 2 percent from 1943, chiefly owing to efforts of companies in the Lake Superior district to ship as large a tonnage of direct shipping ore as possible, thereby meeting shipping quotas with a minimum of manpower input. The ratio of crude ore used to usable ore produced was 1.867:1 in 1944 compared with 1.936:1 in 1943.

Iron ore shipped from mines in the United States, 1925-29 (average), and 1940-44, in gross tons, and percentage of beneficiated ore compared to total shipped

[Exclusive of ore containing 5 percent or more manganese and ore sold for paint]

Year	Beneficiated	Total	Proportion of beneficiated to total (percent)	Year	Beneficiated	Total	Proportion of beneficiated to total (percent)
1925-29 (av.)	8,653,590	66,697,126	13.0	1942	23,104,945	105,313,653	21.9

1941	19,376,120	93,053,994	20.8	1944	20,303,422	94,544,635	21.5

¹ Includes ore for paint.

SINTER

Domestic sintering plants in 1944 used 12,247,501 gross tons of iron ore, 5,406,693 tons of flue dust, 338,270 tons of mill cinder and roll scale, 504,595 tons of pyrites cinder, and 4,096 tons of manganese bearing ore to produce 16,189,097¹ tons of sinter—a yield of 88 percent.

Sinter production in 1944 came from plants at mines, blast-furnace plants, custom mills, and a number of rotary cement kilns converted to iron-ore roasting. Of the sinter produced in the United States in 1944, 22 percent was made at mine plants in 4 States, and 78 percent was produced at blast-furnace plants and custom mills in 14 States.

Production and consumption of sinter in the United States in 1944, by States, in gross tons

AVERAGE VALUE

The average value per gross ton of iron ore at mines was \$2.70 in 1944 and 1943.

The accompanying table gives the average value at the mines of the different classes of iron ore in 1944 for each of the producing

Average value per gross ton of iron ore at mines in the United States, 1943-44

¹ Included with average for all States.

² Included under other States in 1943.

³ Includes Arizona, Colorado, and Utah in 1943 and Nevada in 1944. Also includes Arkansas, California, South Dakota, Texas, Virginia, Washington, and Wyoming in 1943 and 1944.

⁴ Cinder and sinter obtained from pyrites treated in, but not necessarily mined in, States indicated.

States or groups of States, except when there are fewer than three shippers of a certain class of ore in a State and permission was not given to publish the value. These data are taken directly from statements of producers and probably represent the commercial selling prices only approximately, as not all reports are comparable. Some evidently include mining costs only; others contain, in addition, the cost of selling and insuring the ore; others include an allowance for a sinking fund; and still others comprise only costs charged against blast furnaces. None of the reports, however, is supposed to include freight charges.

CONSUMPTION

A total of 99,615,943 gross tons of metallurgical iron ore was reported consumed in 1944. Of this, 83 percent was consumed in iron blast furnaces, 12 percent in sintering plants, 4 percent in steel furnaces, and 1 percent in ferro-alloy furnaces. The 244,275 tons of "paint" and "all other" ore shipped from mines and mills in 1944 were assumed to have gone directly into consumption.

Consumption of iron ore in the United States in 1944, by States and uses, in gross tons

STOCKS OF IRON ORE

Stocks of iron ore at mines on December 31, 1944, decreased 20 percent from 1943. Of the quantity in stock piles, 43 percent was at mines in Michigan, 31 percent in Minnesota, and 3 percent in Wisconsin—a total of 77 percent in the Lake Superior district.

Stocks of crude ore at mines totaled 2,869,226 gross tons on December 31, 1944, compared with 3,934,316 tons in 1943.

Stocks of iron ore at consuming plants totaled 32,914,774 gross tons on December 31, 1944, compared with 38,337,616 tons at the end of 1943. The decrease was a result of the cut-back in Lake shipments to reduce stocks at consuming plants.

¹ Includes pyrites cinder.

² United Kingdom of Great Britain and Northern Ireland.

Exports of iron ore from the United States totaled 2,158,447 gross tons, valued at \$7,163,504 (\$3.32 a ton) in 1944, compared with 2,424,801 tons valued at \$8,117,156 (\$3.35 a ton) in 1943. Of the total quantity of iron ore exported in 1944, Canada received 2,158,425 tons and Mexico 22 tons.

REVIEW OF LAKE SUPERIOR DISTRICT

Production and shipments.—Production of iron ore from mines in the Lake Superior district in 1944 was 6 percent lower than in 1943 and supplied 84 percent of the domestic output compared with 85

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

percent in 1943. The Mesabi was again the largest of the six producing ranges, supplying 70 percent of the district total and 56 percent of the United States total. The Lake Superior iron-ore data do not include production and shipments of 1,172,636 tons of ore containing 5 percent and more manganese.

The Lake Superior Iron Ore Association reported 80,674,010 tons of iron and manganiferous ore shipped to Great Lake ports from United States mines in 1944, a decrease of 4 percent from 1943. All-rail shipments totaled 1,182,995 gross tons in 1944 compared with 2,015,341 tons in 1943.

The first iron ore of the 1944 season was loaded at Escanaba on April 5, and the first at upper Lakes (Two Harbors) was loaded April 9. In 1943, the corresponding dates were April 4 and April 24. The Sault locks were opened by icebreakers on March 31, the average date being April 17. Favorable shipping weather enabled the industry to move large tonnages of ore earlier than in 1943. In April 1944, loadings totaled 5.3 million tons compared with 2 million tons in 1943. Shipments in May and June also exceeded those of the previous year. Thereafter, at the discretion of industry it was decided to decrease stocks of iron ore at consuming plants so that approximately 15 million tons would be on hand April 1, 1945. The effectiveness of the program is shown by the fact that an actual tonnage of 14,996,295 tons were on hand at the designated date. Lake shipments declined steadily after June and resulted in the over-all decrease for the year. The last vessel was loaded at Ashland on November 28 compared with December 6, 1943.

Iron ore produced in the Lake Superior district, 1854-1944, by ranges, in gross tons

[Exclusive after 1905 of ore containing 5 percent or more manganese]

Year	Marquette	Menominee	Gogebic	Vermilion	Mesabi	Cuyuna	Total

The large Lake shipments during 1944 were not made without serious loss of life and property. Two collisions in a Lake Erie fog on April 27 caused the loss of two of the four vessels involved. The *James H. Reed*, an ore carrier with 7,500 tons aboard, went down with the loss of 12 lives. The *Frank E. Vigor*, a self-unloader with 6,000 tons of sulfur, went down without loss of life. Through great engineering skill, the *George M. Humphrey*, sunk by collision in fog in June 1943, was raised during 1944 from its position in 80 feet of water in the Straits of Mackinac. A valuable vessel and half of its cargo of ore were saved.

All ore vessels built by the Maritime Commission and 36 old trade-in boats were in service during 1944. A record movement of grain resulted in a new tonnage record for shipments of all commodities on the Great Lakes. The emergency ore dock built at Escanaba in 1942 was dismantled to provide lumber for more urgent requirements.

Mining developments.—The use of heavy trucks and belt conveyors to replace rail haulage at open-pit mines continued to expand in 1944, and new equipment for this purpose was acquired and placed in service during the year. Expansion and construction of ore concentrating plant facilities continued with new installations of crushing, screening, washing, and concentration equipment. The most spectacular open-pit development was at Embarrass Lake, on the eastern Mesabi range, where construction of a long drainage diversion ditch and dam, pumping of the lake, and stripping a large volume of overburden, were preliminaries to the successful opening of a large-tonnage mine. Underground development during 1944 included shaft deepening at mines on the Vermilion range in Minnesota and in the Wisconsin-Michigan ranges. At the Zenith mine on the Vermilion, the deep 66-inch borehole was enlarged into a rectangular shaft and equipped with a new head frame. A similar hole at the Cary mine on the Gogebic range in Wisconsin was completed, and its conversion to a rectangular shaft was in progress. Construction of the new head frame and mine buildings was underway. At the Pioneer mine on the Vermilion range, a new inclined offset replacing the shifting upper section of the vertical A shaft was completed and put in service.

The Geological Survey, in cooperation with the Michigan Geological Survey Division continued geological studies in the Iron River-Crystal Falls area of Michigan preparatory to further exploration. In a move to stimulate new exploration, the State of Michigan leased 12,000 acres of State-owned land in Dickinson County on 50-year contract to a large operating company.

Average costs, per gross ton, of mining iron ore at underground mines and at siliceous open pits in Michigan in 1944¹

² This figure does not represent true profit, as much ore is sold below the Lake Erie price.

Analyses.—The following table was compiled by the Lake Superior Iron Ore Association.

Average analyses of total tonnages (bill-of-lading weights) of all grades of iron-ore from all ranges of Lake Superior district, 1940-44

Year	Gross tons	Iron (natural)	Phosphorus	Silica	Manganese	Moisture
		Percent	Percent	Percent	Percent	Percent
1940.....	63,308,413	52.09	0.085	8.00	0.77	10.93
1941.....	79,941,240	51.83	.085	8.18	.78	11.01
1942.....	92,069,902	51.65	.089	8.21	.79	10.98
1943.....	85,116,347	51.58	.091	8.32	.82	11.06
1944.....	81,039,404	51.72	.088	8.42	.74	11.02

Stocks at Lake Erie Ports.—On December 1, 1944, just before navigation stopped, the Lake Superior Iron Ore Association reported 5,472,556 tons of iron ore at Lake Erie ports compared with 6,393,581 tons in 1943. At the opening of the 1945 season (May 1, 1945) 1,959,675 tons of ore were in stock at these ports compared with 2,906,827 tons on May 1, 1944. Withdrawals from stocks during this 5-month period in 1944-45 were virtually unchanged from a year ago.

Prices of Lake Superior ore.—The prices established April 17, 1940, for the four standard grades of Lake Superior ore remained unchanged. Since that date the prices of the various grades quoted at Lake Erie ports for a long-ton unit were as follows: Old-Range Bessemer, 9.223 cents; Mesabi Bessemer, 8.932 cents; Old-Range Nonbessemer, 8.932 cents; and Mesabi Nonbessemer, 8.641 cents; respectively, \$4.75, \$4.60, and \$4.45 a gross ton. The base of the four standard grades since 1925 has been an iron content of 51.50 percent natural. For the Bessemer grades, the allowable phosphorus content is 0.045 percent (dry), and for the non-Bessemer grades the phosphorus content ranges from 0.045 to 0.18 percent. Ores containing more than 0.18 percent phosphorus are classed as high-phosphorus ores, whereas those containing 18 percent or more silica are classed as siliceous ores.

Reserves.—The following tables showing reserves of iron ore in Michigan and Minnesota were compiled by the Michigan Department of Conservation and the Minnesota Department of Taxation respectively. The Minnesota tonnage data are used for the purpose of tax assessment. An additional 13,197,467 tons on lands belonging to the State (not taxable) were available on May 1, 1944.

Iron-ore reserves in Michigan, January 1, 1940-45, in gross tons

Range	1941	1942	1943	1944	1945

MINING BY STATES

Alabama.—With the Republic Steel Corp. the only important buyer of brown ore, the total number of mines operating in Alabama declined from 52 in 1943 to 28 in 1944. The Red Mountain group of mines—the Ishkooda, Muscoda, and Wenonah—operated by the Tennessee Coal, Iron & Railroad Co., were the largest producers in the State during 1944. Their underground mines produced hematite, some of which was sintered before consumption, the rest being shipped direct to furnaces. Sinter was also produced at the Republic Steel Corp. Spaulding mine. Hematite from this mine was concentrated and mixed with pyrites cinder from Virginia and other materials before being sintered. Sinter produced from materials other than iron ore has been excluded from Alabama mine statistics but has been credited to sinter production at consuming plants. The Spaulding mine was forced to close down in September for several months because of a break-down of the primary crusher.

Total production of crude brown ore in Alabama in 1944 decreased 8 percent from 1943; virtually all of this ore was washed before shipment for consumption. The ratio of concentration was 5.36:1 in 1944 compared with 5.22:1 in 1943.

The Russellville 5, 11, and 12 and La Grange mines of the Sloss Sheffield Steel & Iron Co., the Giles mine of the Central Iron Ore Co., and the Docray mine of the Shook & Fletcher Supply Co. were the large brown-ore producers in the State.

Usable hematite produced in 1944 averaged 34.57 percent Fe, 0.15 percent Mn, 0.31 percent P, 16.23 percent SiO₂, and 14.68 percent CaO. Washed brown ore in 1944 contained 44.72 percent Fe, 0.55 percent Mn, 0.44 percent P, and 10.70 percent SiO₂.

Arkansas.—A small quantity of magnetite from the Magnet Cove mine in Hot Spring County was shipped for consumption in Alabama blast furnaces in 1944.

California.—Most of the production of iron ore (695,233 tons) in 1944, as in 1943, was hematite from the Vulcan mine near Kelso, San Bernadino County, which shipped to the Fontana furnace. A total of 95,929 tons of magnetite was produced near Redding, Shasta County, and was used as ballast on shipping vessels. Magnetite sand, shipped from a deposit near Watsonville, was also used as ballast. Ballast ore is usually graded according to specific gravity.

Georgia.—All of Georgia's output in 1944 was brown ore and came from eight mines and an undetermined number of small pits in Bartow, Cherokee, and Polk Counties. The largest output was from the Mitchell and Hodge operations in Bartow County.

Michigan and Minnesota.—See Review of Lake Superior District.

Missouri.—Production of iron ore from Missouri dropped from 52,699 tons in 1943 to 19,293 tons in 1944. However, the Iron Mountain mine was reopened in December by the M. A. Hanna Co., and production from this mine is expected to total 250,000 tons in 1945. Concentration by jigging and tabling will produce a product low in phosphorus containing 55 percent iron. Shipments are to blast furnaces at Granite City, Ill.

Nevada.—Most of the ore from Nevada was shipped from Pershing County by Heizer & Segerstrom for ship ballast. Some ore was shipped to the West coast for use in steel furnaces.

New Jersey.—Labor shortages continued to be a major problem in New Jersey during 1944. The Washington mine of the Alan Wood Steel Co. was forced to close in December because of insufficient miners. The employees released were offered the opportunity of employment at the company nearby Scrub Oaks mine.

A total of 1,087,948 tons of crude magnetite was produced from mines (all underground) in New Jersey in 1944. Direct lump ore amounting to 116,163 was shipped during the year. The remainder was concentrated magnetically, and 383,719 tons of concentrates were produced; none was sintered at mine plants.

New Mexico.—The St. Louis Smelting & Refining Co. El Paso iron claim at Hanover, Grant County, supplied the State total in 1944.

New York.—Magnetite was produced from six mines in the Adirondack district during 1944. Except for lump ore, which is used as a charge and finishing ore in open-hearth furnaces, all of the ore was shipped as concentrate or sinter.

The Old Bed-Harmony mine at Mineville was the largest producer. A new concentrator and sintering plant at the Fisher Hill mine was put into operation in 1944, using both Fisher Hill and Mineville ores.

Manpower shortages hindered production during the year as at other northeastern mines. It is established that 1,100 additional employees would be necessary to operate New York mines at capacity. Output in 1944 was at about one-half rated capacity.

The use of diamond-drill blast holes has recently proved satisfactory at Mineville and is finding additional application.

The Clinton Metallic Paint Co. produced hematite in Oneida County for use in paint during the year.

Pennsylvania.—Virtually all the ore from Pennsylvania was magnetite from the underground—open-pit operations of the Cornwall mine in Lebanon County. Ore from Cornwall is shipped to Lebanon, where it is concentrated magnetically and treated further by flotation to remove chalcopyrite, pyrite, and other minerals. Some magnetite concentrates are sintered, and some are shipped to consuming plants for sintering.

Carbonate ore from the Hazard and Little Gap mine in Carbon County was mined by the Prince Manufacturing Co. for use in paint.

South Dakota.—Paint ore was mined from the Iron Lode claims in Pennington County.

¹ In addition there is an undetermined number of small pits. The output of these pits is included in the tonnage given.² Includes output from 1 plant reprocessing tailings.

Texas.—Brown ore was mined from the Lone Star mine in Morris County by the Lone Star Steel Co., and from the North Basin mine in Linden County and the Mount Haven mine in Cherokee County by the Sheffield Steel Co. A very satisfactory open-hearth charge ore was produced by the Lone Star Steel Co., by calcining concentrated brown ore in a rotary kiln. Its blast furnace at Daingerfield had not yet operated in 1944.

Hematite was mined and shipped by Tillie B. Moss from the Moss mine in Llano County.

Utah.—Semi-altered magnetite was shipped from the Iron Mountain, Great Western, Duncan, and Walker Iron Mining (formerly the Excelsior) mines in Iron County. The last mine, operated by Senter F. Walker, was opened in 1944 to supply low-sulfur ore to the Fontana, Calif., blast furnace.

Virginia.—Brown ore produced from the American Pigment Corp. mine at Hiwassee, Pulaski County, constituted the only output from Virginia in 1944. All of the ore was washed before being used in the manufacture of paint.

Washington.—The Napoleon mine in Stevens County shipped hematite for cement manufacture during 1944. Iron ore for ballast was mined at the Neutral mine in Ferry County.

Wisconsin.—See Review of Lake Superior District.

Wyoming.—Hematite for Pueblo furnaces was mined at the Sunrise mine by the Colorado Fuel & Iron Corp. during 1944.

EMPLOYMENT AT IRON MINES

Complete data on employment at iron mines in 1944 are not yet available. Preliminary figures indicate an 18-percent decline in the number of workers from 1943. The average number employed is estimated at 27,200 men, working a total of 63,000,000 man-hours to produce 93,524,797 gross tons of ore—an average of about 1.5 tons per man-hour, an increase of 15 percent over 1943. The increase in efficiency in 1944 over 1943 was largely due to an increase in output at open-pit mines where production is at a much higher rate per man-hour than underground operations.

Increases in production at western open-pit mines also aided the output per man-hour in 1944. These mines which are shallow pits require very little handling of ore and consequently are very efficient in labor requirements.

Employment at iron-ore mines and beneficiating plants, quantity and tenor of ore produced, and average output per man in 1943, by districts and States

¹ In addition to the countries listed Argentina, China, Egypt, Eritrea, Finland, French West Africa, Madagascar, and New South Wales report production of iron ore, but complete data are not available.

² Production of Tofo mines. ³ Data not available. ⁴ Slovakia only. ⁵ Estimate included in total.

⁶ Exclusive of manganeseiferous iron ore carrying 12 to 30 percent manganese. ⁷ Estimate. ⁸ Exports.

⁹ U. S. S. R. in Asia included with U. S. S. R. in Europe. ¹⁰ Croatia only.

¹¹ Exclusive of bog ore, which is used mainly for purification of gas.

¹² January to July, inclusive. ¹³ January to June, inclusive.

REVIEW BY COUNTRIES

Canada.—Shipments of iron ore from Canadian mines totaled 498,635 gross tons in 1944. This quantity, included 482,083 tons of sinter from the Helen mine in the Michipicoten district and 16,552 tons of ore from the new Steep Rock mine on the Atikokan range of western Ontario. Steep Rock shipments in 1944 were from a United States port, but a new ore dock at Port Arthur is expected to be completed in time for the 1945 season when shipments from this mine will be greatly increased. A new operation is expected to be in production during 1944—the Josephine-Ruth property of Michipicoten Iron mines, Ltd. The Josephine will ship hematite, whereas siderite, similar to Helen ore, will be mined at the Ruth.

Chile.—The important iron-ore operation in Chile is the Tofo mine near La Serena, Province of Coquimbo. The output from this open-pit mine in 1944 totaled 663,879 gross tons compared with 294,684 tons in 1943. Of the 1944 production, 17,660 tons were shipped to blast furnaces at Corral near Valdivia, and the remainder was stock-piled.

Cuba.—In 1944, 27,922 gross tons of iron ore were produced from the Daiquiri open-cut mine in Oriente Province; all was stock-piled. For the 10-year period ended in 1941 annual shipments of iron ore from Cuba averaged 243,086 tons. This was reduced to 18,043 tons in 1942, when war shipping limitations prevented further movement of iron ore from Cuban ports. Stocks totaled 291,171 tons at the end of 1944 compared with 263,345 tons in 1943.

Iron ore shipped from mines in the Province of Oriente, Cuba, 1884-1944, in gross tons

Year	Juragua, Daiquiri, and Estancia (hematite and magne- tite)	Sagua (hematite)	Mayari (brown ore)	Guama (hematite)	El Cuero (hematite)	Total
1884-1942.....	22, 503, 074	20, 438	3, 988, 694	41, 241	903, 103	27, 456, 550
1943.....			96			96
1944.....	22, 503, 074	20, 438	3, 988, 790	41, 241	903, 103	27, 456, 646

Labrador.—A report of the field work done intermittently by the Hollinger Consolidated Gold Mines, Ltd., since 1936 has recently been made public.³ During 1944, diamond drilling was done at Sawyer Lake, situated 300 miles north of Seven Islands, a town on the Gulf of St. Lawrence. One hole, bottomed at 220 feet, was reported still in high-grade ore averaging 68.4 percent iron. Retty has estimated the quantity of ore at 30,000 tons per vertical foot.

At present the deposits are inaccessible, requiring the construction of a railroad 350 miles in length.

Mexico.—Imports of iron ore from Mexico totaled 62,630 gross tons in 1944.

One of the most important iron-ore deposits of Mexico is at Cerro de Mercado, just north of Durango. The reserves of ore available

³ Retty, J. A. Surface Work Indicates Possibility of a Major Iron Ore Field in Central Labrador: Min. and Met., vol. 26, No. 461, May 1946, p. 256.

have been estimated at 76,300,000 tons⁴ of hematite, martite, and magnetite. Production from this deposit to date has totaled approximately 2,000,000 metric tons. The maximum annual output (1942) was 160,180 tons. The ore is mined by open-pit methods and averages 62 percent iron, 0.5 percent phosphorus, and 0.5 percent sulfur. Most of the ore from this operation moves 386 miles to the steel plant of the Cia. de Fierro y Acero de Monterrey, S. A. A small tonnage is distributed among local consumers and the Texas Mining & Smelting Co.

North Africa.—The principal property in Spanish Morocco is the Minas del Rif, which lies about 13 miles southwest of Melilla. East of the Rif mines are the Minas de Setolazar, a substantial producing area but one that yields lower-grade ore. In Algeria good rail and shipping facilities exist, and large quantities of iron ore have been shipped in normal times from Bone, Beni Saf, Bougie, and Algiers. The most important operation in Algeria is the Ouenza mine 87 miles by rail from Bone and operated by the Soc. de l'Ouenza. A lumpy, low-phosphorus ore is shipped from the Timezrit mine 25 miles south of the port of Bougie. Iron ore shipped from Algiers comes from the Zaccar mines about 62 miles inland. Most of the Algerian ore consists of red and brown hematites rich in iron and low in silica. Some manganiferous ore is produced from the Rur-el Maden mine in western Oran.

GENERAL SUMMARY

The steel industry established a production record in 1944 that is likely to stand for many years. Output of steel ingots and castings totaled 89,641,600 net tons, compared with 88,836,512 tons in 1943. Plant expansion permitted this record steel production with an average operating rate of 96 percent of capacity compared with 98 percent in 1943. Pig-iron output in supporting this steel production also established a new record—excluding ferro-alloys it totaled 61,003,759 net tons. A 19-percent decrease in alloy steel production was largely due to declines in the lower-content grades so that the decline in the demand for ferro-alloys was less pronounced; a 7-percent decrease in production of ferro-alloys was recorded in 1944. The steel supply-demand relationship during 1944 was generally satisfactory, with the industry able to meet most military and highly essential civilian demands while operating at a rate slightly lower than the previous year.

Shipbuilding, although receiving 10 percent less steel, continued to be the leading consumer during 1944. Shipments to this industry totaled 10,287,299 net tons in 1944 compared with 11,508,809 tons in 1943. Miscellaneous industries and exports, largely arms production and lend-lease shipments, together received the largest share of the year's steel output, as in 1942 and 1943. Agriculture, railroads, and jobbers and dealers were allocated considerably more steel in 1944, receiving 57 percent, 20 percent, and 18 percent more steel than in

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

1943. Cut-backs in mobile equipment for the fighting forces resulted in a 20-percent decrease in steel shipments to the automotive and aircraft industries.

Total output of munitions in 1944 was valued at 63.7 billion dollars, an increase of 12 percent over 1943. However, advancements during the course of the year were small, and the over-all increase resulted from maintaining the high rate of output established in the final quarter of 1943. The largest increases in production were apparent in the aircraft industry. Total output of planes in 1944 numbered 96,356 compared with 85,930 in 1943; total weight of aircraft produced increased 47 percent over 1943. Next to aircraft, the largest increase was in the ammunition group. This change resulted from new demands among major types of ammunition, with particular emphasis

FIGURE 1.—Trend in production of pig iron in the United States, 1880-1944.

on aerial bombs. At the close of the year the stress was on heavy artillery, shells and rockets, and some small-arm lines. In the Navy program the trend was away from antisubmarine vessels to landing craft for the projected 1945 and 1946 offensives. Among the merchant types, the trend was from Liberty vessels to the faster cargo ships and to military types. Military vessels require a larger steel input per ton of ship capacity than the mass-produced Liberty ships. There was a sharp reduction in the combat and motor vehicle group in 1944, entirely due to the cut-backs in tanks, armored cars, and personnel carriers.

Employment in the iron and steel industry continued to drop during 1944. Total wage earners decreased from 503,000 in January to 474,000 in November. The average workweek increased, however, and was 46.6 hours in November compared with 45.6 hours in January. Average weekly earnings increased steadily from \$52.19 in January to \$54.55 in November.

POSTWAR OUTLOOK

A prospective decline in military requirements following V-E day will have a marked effect on steel-ingot production. During as early as the third and fourth quarters of 1945 it is anticipated that military and essential civilian requirements, although high, will center on fewer steel shapes. Virtual capacity operation of steel plants equipped to produce these items is expected, whereas plants not so equipped will be in an unsatisfactory position until they are able to convert to meet other civilian demands. Chief among products to be drastically curtailed is ship plate, which was extremely critical in the early days of the war,—a fact that led to the construction of 2,800,000 net tons of plate-rolling capacity during the war. Requirements for ship plate are expected to drop to approximately 10 percent of peak war-time output by the close of 1945. Shell steel and alloy steels will also be in considerably less demand during the second half of 1945. Increased demands for strip, sheet, and structures will aid the position of plants producing these products.

The automobile industry, steel's leading prospective customer for the postwar period, was making preparations in 1944 for the tremendous task of reconverting to meet civilian requirements from 100 percent war production. Shortly after V-E day, the industry was given permission to produce a limited number of passenger cars during the last half of 1945—the first output since March 1942. As of June 1945 only about 215,000 units were planned for 1945, but it was anticipated that production will reach a rate of 2 to 3 million automobiles

per year by the close of 1946. Peak automobile production of 5 million units in prewar years required 7 million net tons of steel products, or about 10 million tons converted to ingots. This rate of operation is virtually a certainty as a minimum for the immediate postwar years.

The railroads, with plans to invest 1,750 million dollars in rolling stock and a similar amount in other facilities during the 5 post-V-E years, will rival the automobile industry as a consumer of steel. Railroads received 5.4 million tons of steel products in 1944 compared with 4.5 million tons in 1943 and 3.8 million in 1940. Light metals will enter this field to some extent in the manufacture of lightweight freight and passenger cars, but the total tonnage of steel that will be thus displaced will be relatively small.

The construction industry has a backlog of \$10.5 billion awaiting the relaxation of manpower and materials restrictions. Approximately \$4 billion will be expended during 1945 according to recent War Production Board estimates. This industry received 4.5 million tons of steel products in 1944, and postwar requirements will probably exceed this figure.

The container industry, which in 1944 used 3.7 million tons of steel products, largely tin and terne plate, will continue to be a large consumer, with requirements virtually unchanged.

Production of essential civilian items such as farm machinery, trucks, locomotives, and mining equipment, which has already been stepped up will accelerate during continuation of the Japanese War.

Manufacturers of such consumer appliances as electric irons, washing machines, stoves, and kitchen appliances, some of which are being produced in limited quantities, will be pressed to capacity following V-J day to meet postponed civilian requirements.

Summarizing steel made available by cut-backs in war-material output will be diverted to civilian production as fast as and to the extent that fabricating industries are able to absorb it. However, it is not expected that such industries will be able to use a tonnage approaching that required during World War II. Nor is it anticipated that requirements for steel will revert to the prewar (1935-39) level of 46,574,000 tons. The rate at which steel furnaces will be producing at the close of the war in Asia will depend largely on how soon hostilities terminate there. The annual production of steel ingots and castings for the 5 years following Japan's capitulation will probably average about 60 million net tons. At this rate, the pig-iron requirements for iron and steel furnaces would approximate 40 million tons.

PIG IRON

PRODUCTION AND SHIPMENTS

Domestic production of pig iron in 1944, exclusive of ferro-alloys, increased slightly (less than 0.5 percent) over 1943 to establish a new record. The output in 1944 comprised 60,944,293 net tons using coke and 59,466 using charcoal as fuel. Pennsylvania was the largest producer of pig iron in 1944 with 30 percent of the total; Ohio ranked second with 22 percent.

¹ American Iron and Steel Institute.

CONSUMPTION OF METALLIFEROUS RAW MATERIALS

The production of pig iron in 1944 required 109,531,216 tons of iron ore, sinter, and manganiferous iron ore, 3,544,025 tons of mill cinder and roll scale, 3,518,855 tons of open-hearth and Bessemer slag, 2,135,498 tons of purchased scrap, 146 tons of pyrite cinder, and 49,901 tons of miscellaneous material, an average of 1,947 tons of metalliferous materials (exclusive of home scrap and flue dust) per ton of pig iron made.

Of the pig iron manufactured in 1944, it is calculated that 119,120 tons valued at \$2,405,500 were made from 255,449 tons of foreign ores, including ore from Africa, Canada, Cuba, Mexico, and Sweden, indicating an average yield of 46.63 percent from imported ore. Domestic ore and sinter (109,374,151 tons) and other materials (9,248,425 tons) totaling 118,622,576 tons were reported as used in the manufacture of 60,884,639 tons of pig iron, indicating an average pig-iron yield of 51.33 percent from domestic materials. In addition, 1,519,226 tons of home scrap and 129,166 tons of flue dust were consumed in making pig iron in 1944.

The iron ore used in Alabama (all domestic) in 1944 was mainly hematite from mines in Jefferson County. However, brown ore from Alabama and Georgia also was used. In addition, ferruginous manganese ore of both domestic and Cuban origin, amounting to 21,451 and 1,844 tons, respectively, was used. Because the average grade of ores used in Alabama is low, furnaces in this State use more ore per ton of pig iron than any other district in the United States.

The iron ore used in Fontana, Calif., furnace was hematite supplied by the Vulcan mine in San Bernardino County, Calif. Manganese-bearing ore of both domestic and Mexican origin also was used.

¹ Excludes recycled materials.

Maryland furnaces consumed chiefly domestic ore in 1944, but some iron ore from Africa and pyrite cinder of both domestic and foreign origin were used. These furnaces have a low consumption of ore per ton of pig; however, they used proportionately more miscellaneous materials than any other State.

Blast furnaces in Illinois, Indiana, Kentucky, Michigan, Minnesota, and West Virginia used Lake Superior iron ore and manganese ferrous iron ore almost exclusively.

In New York the furnaces in the Buffalo district used ore from the Lake Superior district and Canada, and magnetite from New York; the furnace at Troy consumed magnetite sinter from the Chateaugay mine at Lyon Mountain, N. Y.

Ohio blast furnaces consumed magnetite sinter from New York in addition to hematite from the Lake Superior district.

Virtually all the ore consumed in western Pennsylvania furnaces came from the Lake Superior district. Those in the eastern part of the State used some Lake ore, some magnetite ores from Pennsylvania, New Jersey, and New York, and some ore from Africa.

The Colorado furnaces used hematite from the Sunrise mine in Wyoming, semialtered magnetite from the Duncan mine (Utah), and magnetite and manganese-bearing ores from New Mexico.

The Provo, Utah, furnace used semialtered magnetite from the Iron Mountain mine near Cedar City, Utah, and manganese-bearing ores, chiefly from Nevada and Utah. The sinter used was produced at Geneva and Provo from Iron Mountain fine ore.

VALUE AT BLAST FURNACES

The average value of all grades of pig iron given in the following table is based upon reports of producers to the Bureau of Mines. The figures represent the values f. o. b. blast furnaces and do not include the values of ferro-alloys. The general average value for all grades of pig iron at the furnaces was \$20.97 a net ton in 1944—virtually unchanged from 1943.

Average value per net ton of pig iron at blast furnaces in the United States, 1939-44, by States

State	1939	1940	1941	1942	1943	1944
Alabama.....	\$14.42	\$14.30	\$17.25	\$17.30	\$17.35	\$17.34

CONSUMPTION

Consumption of pig iron in 1944 increased 1 percent over 1943. Pig iron, a product of the blast furnace, is a semiraw material and, except for the small quantity used in direct castings, moves to steel- or iron-melting furnaces for further refining alone or mixed with other ingredients. In 1944, 89 percent of the pig iron went to steel-making furnaces (open-hearth, bessemer, and electric) to be processed into steel. Direct castings took 4 percent of the 1944 total, and the remaining 7 percent was consumed in iron-making furnaces, of which the cupola is the most important. The consumption of pig iron, by types of furnace, for 1941 to 1944 is shown in the following table. The quantities of pig iron used in these furnaces are supplemented by the addition of ferrous scrap. The proportion of pig iron to scrap used in steel furnaces increased in 1944 over 1943.

Consumption of pig iron in the United States, 1941-44, by type of furnace

¹ Some pig iron used in making direct castings included in cupola.

² Less than 0.05 percent.

Plants using pig iron are situated in all 48 States, the District of Columbia, and Alaska. As expected from the uses of pig iron, consumption is concentrated largely in the steel-making centers of the North Central, Middle Atlantic, and Southeastern States. These areas in 1944 used about 97 percent of the pig iron, Pennsylvania (the leading consumer) taking about 31 percent of the total and Ohio (the second-largest consumer) 20 percent.

¹ Pig iron is produced in Chile, New Zealand, Philippine Islands and Switzerland, in addition to countries listed, but production figures are not available.

² Year ended June 30.

³ Data not available; estimate included in total for 1940.

⁴ Estimate.

⁵ Approximate production as published by Iron Age, vol. 147, No. 1, Jan. 2, 1941, p. 61.

⁶ Estimated production includes Manchuria.

⁷ Unoccupied China.

⁸ Approximate production as published by Steel, vol. 196, No. 1, January 1940, p. 269.

⁹ Included in German figure in 1940.

¹⁰ Beginning with March 1935, production of the Saar included with that of Germany.

¹¹ Croatia only.

FERRO-ALLOYS

PRODUCTION AND SHIPMENTS

The production of ferro-alloys in 1944 totaled 1,893,855 net tons compared with 2,032,979 tons in 1943—a decrease of 7 percent. In 1944 ferro-alloys were made at 15 blast-furnace plants, 27 electric-furnace plants, and 3 aluminothermic plants. The 27 electric-furnace plants include 5 plants that made ferrophosphorus and 2 plants that made ferrosilicon as a byproduct. Shipments of all classes of ferro-alloys in 1944 decreased 5 percent in quantity and 9 percent in value from 1943. Pennsylvania was by far the largest producer and shipper of ferro-alloys in 1944, both in tonnage and value. Of the ferro-alloys shipped in 1944, Pennsylvania contributed 37 percent of the total tonnage and 45 percent of the total value; New York was second, with 17.4 percent of the tonnage and 22.6 percent of the value.

Ferro-alloys produced and shipped from furnaces in the United States, 1943-44

¹ Silicomanganese, manganese briquets, ferrochromium, ferrocolumbium, ferroboreon, zirconium-ferro-silicon, and alsifer; also chrome-manganese in 1943 and grainals and stiminal in 1944.

Ferromanganese.—The output of ferromanganese in 1944 averaged 78.62 percent manganese and came from nine blast-furnace plants and two electric-furnace plants. Of the manganese ore used in 1944 in the manufacture of ferromanganese, 90.3 percent was from foreign sources. During 1944 steel producers used 13.2 pounds of metallic manganese as ferro-alloys per ton of steel produced. Of this quantity, 11.7 pounds were in the form of ferromanganese. A total of 730,491 tons of ferromanganese was consumed during the year—virtually all by the iron and steel industry. A detailed discussion of manganese alloys is contained in the chapter on Manganese.

Spiegeleisen.—In 1944, 165,530 net tons of spiegeleisen, averaging 19.6 percent manganese, were produced; all was made in blast furnaces. This represents an increase of 11 percent over 1943. Shipments in 1944 were 155,325 tons valued at \$4,851,490. The average price of spiegeleisen, f. o. b. furnaces, was \$31.23 per net ton in 1944 compared with \$32.16 in 1943.

Ferrosilicon.—Ferrosilicon, including silvery pig iron, is one of the major products of the ferro-alloys industry both with reference to tonnage produced and dollar value. Of the 700,358 net tons of ferrosilicon produced in 1944, 255,399 tons were produced in blast furnaces, 444,215 tons in electric furnaces, and 744 tons as a by-product in the manufacture of artificial abrasives in electric furnaces. The silicon content of the output in 1944 ranged from 9 to 95 percent and averaged 31.2 percent. Blast-furnace production averaged about 10 percent silicon. A break-down of the ferrosilicon and silvery pig iron produced in 1944, by grades, shows that 56 percent (392,483 tons) contained 9 to 16 percent silicon, 31 percent (217,939 tons) averaged 25 to 50 percent silicon, 11 percent (74,749 tons) averaged 71 to 80 percent silicon, and 2 percent (15,187 tons) was made up mostly of grades higher than 80 percent in silicon. Shipments of all grades of ferrosilicon in 1944 amounted to 686,895 tons valued at \$39,531,552.

Ferrosilicon has many uses. In the steel industry, the most important consumer, ferrosilicon is used as a deoxidizer and degasifier to reduce blowholes and to produce sound steel. The 15-percent grade (silvery pig iron) is used as a furnace deoxidizer and scavenger prior to the use of more expensive alloys. Fifty-percent ferrosilicon, the

most commonly used grade, serves primarily as a deoxidizer in the manufacture of practically all kinds of steel, whereas the 75-percent grade is used extensively in the manufacture of steels for automobile and railway springs where a relatively high silicon content is desirable. When large additions of silicon are made to steel, ferrosilicon in the most concentrated form (80 to 95 percent silicon) is employed so as to avoid the chilling effect of adding large masses of cold alloy to the molten metal.

Other significant uses of ferrosilicon are in the (1) manufacture of iron castings (silvery pig iron), (2) manufacture of magnesium (75 percent ferrosilicon), (3) manufacture of hydrogen (85 percent ferrosilicon), and (4) beneficiation of low-quality ores (15-percent ferrosilicon). In the beneficiation process, finely ground 15-percent ferrosilicon is added to water and agitated—the resulting fluid floats a part of the feed, which may be either the valuable portion or the waste.

Ferrosilicon is made of domestic raw materials. To produce 1 net ton of standard (50-percent) ferrosilicon the following materials and power are required: 45 to 55 pounds of electrodes, 1,000 pounds of steel scrap, 1,300 pounds of coke, 2,000 pounds of quartz, and 5,000 kilowatt-hours of electrical energy. The amounts of materials vary in making other grades. Steel scrap is required in proportionately less amounts in the higher-silicon alloys, whereas the amount of coke, quartz, and power required increases rapidly as the silicon content increases. Approximately double the amount of these three is required to produce 75-percent ferrosilicon as is required to produce 50-percent.

Ferrophosphorus.—All ferrophosphorus in 1944 was produced as a byproduct of the electric furnaces in the manufacture of phosphate fertilizers and other chemicals. Shipments amounted to 7,504 net tons valued at \$473,084.

Ferrotungsten.—Production of ferrotungsten dropped from 7,561 net tons in 1943 to 6,696 tons in 1944—a decrease of 11 percent. Shipments in 1944 contained 76.77 percent (10,611,482 pounds) of tungsten and were valued at \$1.863 per pound of contained metal. All ferrotungsten was produced in electric furnaces. Both foreign and domestic ores were used in 1944.

Ferrochromium.—The industrial consumers of ferrochromium reported using 159,911 net tons of ferrochromium in 1944 compared with 183,019 tons in 1943 and 162,904 tons in 1942.

Ferromolybdenum.—The bulk of the ferromolybdenum produced in 1944 was made by the aluminothermic process. Virtually all was produced from domestic ores. However, a small quantity of Canadian ore was imported into the country, converted into molybdenum products, and then exported.

Molybdic oxide, calcium molybdate, and molybdenum compounds.—As these products are used as alloying agents in the production of iron and steel, they are included with ferro-alloys. In 1944 these compounds averaged 55 percent Mo compared with 53 percent in 1943. These materials are considerably less expensive than ferromolybdenum and consequently are used to a greater extent.

Ferrotitanium.—The bulk of the ferrotitanium produced in 1944 was made in electric furnaces, but some was produced by the aluminothermic process. The ferrotitanium produced in 1944 averaged 20 percent titanium, and both foreign and domestic ores were consumed in its manufacture. Ferrotitanium is used chiefly as a deoxidizer

FOREIGN TRADE

Imports and exports of the rarer metals are not recorded separately but are grouped as shown in the following tables. Ferrosilicon comprised most of the imports in both 1943 and 1944.

Ferro-alloys and ferro-alloy metals imported for consumption in the United States, 1943-44, by varieties

Variety of alloy	1943			1944		
	Gross weight (net tons)	Content (net tons)	Value	Gross weight (net tons)	Content (net tons)	Value

STEEL

GENERAL FEATURES

Steel production continued at a high rate throughout 1944, furnaces operating at an average of 96 percent of capacity for the year. Capacity for producing steel increased 2,928,000 net tons to reach a new record total of 93,565,000 tons. Total production of steel in the

United States in 1943 was 89,641,600 tons, a record output. Of the total, 89.7 percent was made in open-hearth furnaces, 5.6 percent in bessemer converters, 4.7 percent in electric furnaces, and only 25 tons in crucible furnaces. In 1944, 90.6 percent of the domestic steel output was made in furnaces in the Northeastern district, 4.5 percent in the Southern district, and 4.9 percent in the Western district compared with 92.5 percent, 4.3 percent and 3.2 percent, respectively, in 1943.

The data concerning steel production used by the Bureau of Mines are furnished by the American Iron and Steel Institute. The output from steel foundries that do not produce steel ingots is not included in the statistics.

Steel capacity, production and percent of operations, 1940-44, in net tons ¹

[Ingots and steel for castings ²]

Years	Capacity	Production					Percent capacity

Steel electrically manufactured in the United States, 1940-44, in net tons

[Includes only that portion of steel for castings produced in foundries operated by companies manufacturing steel ingots]

Year	Ingots	Castings	Total	Year	Ingots	Castings	Total
1940.....	1,608,032	91,974	1,700,006	1943.....	4,473,377	115,663	4,589,070
1941.....	2,758,611	110,645	2,869,256	1944.....	4,131,703	105,996	4,237,699
1942.....	3,843,757	130,783	3,974,540				

The steel output for 1944 includes 10,633,086 net tons of alloy-steel ingots and castings, which represents 12 percent of the total. This figure includes steels in which the minimum of the range specified in one or more of the elements named exceeds the following percentages: Copper, 0.60 percent; manganese, 1.65 percent; silicon, 0.60 percent; aluminum, chromium, cobalt, columbium, molybdenum, nickel, titanium, tungsten, vanadium, and zirconium, any percentage. The output of alloy steels in 1944 decreased 19 percent, whereas steel increased over 1943. Of the total alloy-steel output in 1944, 61 percent came from basic open hearths, 5 percent from acid open hearths, 34 percent from electric furnaces, 23 tons from crucible furnaces, and none from Bessemer converters.

From the accompanying tables it will be seen that most of the steel made in electric furnaces (86 percent in 1944) is alloy steel. Typically, steels with higher alloy content are made in electric furnaces and steel with lower alloy content by the open-hearth process.

Alloy-steel ingots and castings manufactured in the United States, 1940-44, by processes, in net tons

CONSUMPTION OF METALLIFEROUS MATERIALS

During 1944 steel furnaces used 6,228,384 net tons of ores (excluding mill scale) and sinter. Of this quantity 12,565 tons were foreign, originating in Africa, Mexico, and Sweden.

Both charge ore and feed ore are used in the basic open-hearth process. Charge ore is added to furnish oxygen to the charge before it is melted. This ore should be low in both combined and uncombined moisture, silica content, and fines. Ore containing high quantities of silica requires large additions of limestone and consequently produces large volumes of slag, which are expensive and reduce furnace efficiency.

Feed ore, which is added to the heat during the working period, should be hard, dense, coarse, and low in moisture. Although moderately high silica ore can be used as feed ore it is undesirable, as in charge ore, because of the larger quantity of slag necessitated.

Lump ore, which is preferred as feed ore, commands a high price because it is usually mined by underground methods, and the supply is limited.

Sintered pyrite ash and sintered iron ore frequently are used as charge and feed ores. However, these materials are less dense than lump ore and lower in oxygen content. Consequently, more sinter is required to accomplish the same amount of oxidation.

The following table was compiled from Bureau of Mines surveys.

Metalliferous materials consumed in steel furnaces in the United States in 1944, by districts, in net tons

District	Iron ore		Sinter	Manganese ore		Ferro-alloys	Iron and steel scrap		Pig iron
	Domestic	Foreign		Domestic	Foreign		Home	Purchased

GENERAL SUMMARY

A new steel-production peak (89,641,600 short tons), supported by ample supplies of manganese ore, resulted in a continued record activity in the manganese industry during 1944. Although imports of manganese ore decreased 19 percent from 1943, the total supply (imports plus domestic mine shipments) totaled 1,405,177 tons and was only 12 percent lower than consumption. Stocks of ore containing 35 percent or more manganese at the close of 1944 were sufficient to last 13 months at the 1944 average monthly consumption rate.

Production of domestic manganese ore containing (natural) 35 percent or more manganese in 1944 was the largest since 1918 and was the second most productive year on record. Output as measured by shipments from mines totaled 247,616 short tons in 1944 compared with 205,173 tons in 1943 and 190,748 tons in 1942. Shipments of ferruginous manganese ore (10 to 35 percent manganese) amounted to 297,136 tons, and shipments of manganiferous iron ore (5 to 10 percent manganese) were 1,190,476 tons compared with 471,593 tons and 1,251,275 tons, respectively, in 1943. The value of manganese ore shipments in 1944 totaled \$9,014,875 (\$36.41 per short ton) compared with \$7,278,758 (\$35.48 per ton) in 1943.

During 1944 various Government agencies in cooperation with industry were active in planning a stock-piling program for strategic minerals and metals, including manganese. Details of the present status of stock-piling legislation are presented in the chapter of this volume on the Review of the Mineral Industries in 1944.

¹ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Salient statistics of the manganese industry in the United States, 1925-29 (average) and 1940-44, in short tons.

¹ Includes small quantity of miscellaneous ore.

² Imports for consumption.

³ Manganese content.

⁴ Includes small quantity of other manganese alloys.

FIGURE 1.—Imports and domestic production (mine shipments) of manganese ore, 1900-1944. Statistics on imports shown in the graph represent general imports for 1900-1933, imports for consumption adjusted for changes in bonded warehouse stocks for 1934-39, and general imports for 1941-44.

Government purchases continued at a high rate during 1944. On September 1, 1944, the Metals Reserve Company issued new regulations to affect all contract and small-lot purchases of domestic manganese ore made after December 31, 1944. The specifications were relatively severe and forced the closing of the shippers that depended on the Government to purchase their product. Although the new schedule is more severe with regard to specifications, the prices for certain grades of ore are considerably higher than previously. For example, the base price for 42-percent ore under the new schedule is

\$39.06 per long dry ton compared with \$27.30 under the terms of the previous schedule effective since May 4, 1942. However, the rate for 48-percent ore is unchanged at \$1 per unit or \$48 per ton. The price regulations affecting purchases of small lots of manganese ore are identical to the contract specifications except that concentrates are acceptable only on a negotiated basis.

A brief comparison in the prices (disregarding penalties) under the old and new schedules follows. Penalties that are more severe than before will lessen to some extent the advantage of a higher basic rate.

Metals Reserve Company prices for domestic manganese ore under 1945 schedule compared with schedule effective from 1942 to 1945

Grade (percent Mn dry)	Price per long dry ton		Grade (percent Mn dry)	Price per long dry ton	
	Old	New		Old	New
54-----	\$54.00	\$55.62	46-----	\$36.80	\$45.08
52-----	52.00	53.04	44-----	35.20	42.24
50-----	50.00	50.50	42-----	27.30	39.06
48-----	48.00	48.00			

Price regulation.—Ceiling prices for manganese ore remained unchanged at 90 cents per long-ton unit at New York, Philadelphia, Baltimore, Norfolk; 85 cents at Mobile and New Orleans; 96 cents at Fontana, Calif.; Provo, Utah; and Pueblo, Colo.

Regulation 248 prescribes maximum prices for metallurgical manganese ores. Amendment 4 to the regulation was issued April 10, 1944, exempting deliveries of manganese ore in quantities not exceeding 500 pounds. The amendment was issued to cover small quantities of ore shipped for experimental purposes by educational and private laboratories and industries.

New operations.—Domestic production of manganese ore was bolstered by three new operations that contributed 46,183 short tons of concentrates and nodules during 1944. A brief discussion of these operations follows:

The leaching and nodulizing plant of the Manganese Ore Co., Las Vegas, Nev., closed down on September 30, 1944, after producing 13,963 tons of nodules since operations were begun in October 1943. Slightly over 500 men were released at the close of operations, and a very few stayed on to study the process further. This plant, which was designed to produce 100,000 tons of nodules annually, failed to reach anything near capacity operation. The operation was marked by a series of mechanical failures and problems, many of which might have been obviated through experimentation with a pilot plant of relatively small capacity. The company officials believe that the process was technically sound but that the facilities did not prove to be suited to the operation.

The Defense Plant Corporation custom concentrator at Butte, Mont., began operations during January 1944, with the Domestic Manganese & Development Co. as agent for Metals Reserve Company. Manganese oxide and carbonate ores from Philipsburg were treated. However, it was discovered that flotation was more satisfactory using carbonate ores alone, and the use of oxides was discontinued. During the course of the year this mill produced (dry)

19,277 net tons of nodules averaging 51.02 percent Mn, 3.4 percent Fe, 12.02 percent SiO_2 , and 0.48 percent P.

The largest shipment of manganese concentrates in the United States during 1944 came from the Old Dominion mine in Augusta County, Va., operated by the Dominion Manganese Corp., New York City. Shipments from this mine during 1944 totaled 12,943 short tons of psilomelane ore averaging (natural) 41.93 percent Mn, 3.83 percent Fe, 10.82 percent SiO_2 , 0.159 percent P, and 4.17 percent moisture. The ore is mined by open-pit methods and concentrated by log washing, hand sorting, and jigging.

POSTWAR OUTLOOK

Victory in Europe followed by an inevitable easing of Atlantic shipping will secure the position of the United States with regard to manganese ore. Supplies from the Soviet Union, which were completely cut off during the European war, are expected again to enter the trade, and shipments from Brazil, Gold Coast, and Union of South Africa will experience the advantages of peaceful seas. A slackening of steel production beginning in 1945 will improve the Nation's manganese supply-demand relationship further.

Requirements for manganese ore probably will drop gradually from the 1943-44 level of 1,600,000 short tons per year to about 1,000,000 tons after V-J Day. This, however, does not necessarily foreshadow an immediate cutback in domestic production to prewar levels. Some important operations started during the war are expected to continue. The degree to which this is true will depend upon future trade policies and the extent to which operators of relatively high cost milling installations will have been able to reduce their investment cost. A 1,000,000-ton consumption rate is about 50 percent higher than the prewar (1935-39) average and should offer a broader market for any domestic ore that can compete on a specification and price basis.

Work has continued during the war with an aim to make the United States self-supporting in manganese by developing new methods of concentrating such low-grade materials as the manganese-bearing shales at Chamberlain, S. Dak. Research has indicated that the Nation could procure adequate supplies of high-grade material from this source at a relatively high cost, but a competitive product is not in prospect for the next pentad.

Increased use of electrolytic manganese in the ferrous field and the discovery of new uses, accelerated during the war, are expected to continue. Marked increases in the demand for this material during the closing months of 1944 taxed the ability of producers to supply sufficient metal; a new producer of electrolytic manganese, the Olympic Mines, Inc., Hoodspoor, Wash., entered the field in 1944, and interest has been indicated by others. Production costs of electrolytic manganese should decline as demand and output increase.

DOMESTIC PRODUCTION

The following table shows the various types of manganiferous materials shipped by domestic producers from 1940 to 1944:

Manganiferous raw materials shipped by producers in the United States, 1940-44, in short tons

Year	Metallurgical ore				Battery ore	Miscellaneous
	Manganese ore (35 percent or more Mn)	Ferruginous manganese ore (10 to 35 percent Mn)	Manganiferous iron ore (5 to 10 percent Mn)	Manganiferous zinc residuum		
1940	30,416	358,406	914,526	172,990	10,383	4,137
1941	73,852	512,162	918,725	282,049	11,309	2,543
1942	177,966	265,663	1,500,613	292,051	15,410	473
1943	195,096	468,862	1,251,275	270,328	12,704	104
1944	241,170	296,981	1,190,476	247,402	6,224	377

Shipments of various grades of manganese-bearing ores during the last 5 years are given, by States, in the following tables. In addition, battery-grade ore was produced from Montana; a small quantity of miscellaneous ore came from South Carolina and Virginia; and manganiferous zinc residuum was produced from New Jersey zinc ores.

MINING BY STATES

Alabama.—The shipment of manganese ore averaging (dry) 46.51 percent Mn from Alabama in 1944 came from the Cobalt Hill mine in Cherokee County.

Arizona.—The output of manganese ore from Arizona increased 47 percent over 1943. The Black Warrior mine, Mohave County (Artillery Peak district), shipping 1,672 short tons, was the largest operation. The American mine in Gila County was second with 1,384 tons. Counties supplying manganese ore in 1944 were Cochise, Coconino, Gila, Mohave, Navajo, Pima, Santa Cruz, Yuma, and Yavapai. Three mines in Gila County supplied the ferruginous manganese ore.

Arkansas.—The Arkansas Manganese Co. and the Walter H. Denison Manganese & Contracting Co., both of Batesville, continued to be the predominant manganese-ore shippers in Arkansas during 1944. Except for a very small shipment of ore from Polk County, all the output of manganese ore and ferruginous manganese ore came from Independence County. Included in the shipments of ferruginous ore are 5,218 short tons of stock-pile ore which was accumulated by the Metals Reserve Company for concentrating, but which was shipped in 1944 to blast furnaces in the Birmingham district. It was impossible to assign this tonnage to individual mines.

California.—The Buckeye mine in Stanislaus County continued to be the largest producer in the State in 1944. Shipments from this mine totaled 3,997 short tons averaging (dry) 37.50 percent Mn. Mines in 19 counties furnished the State total in 1943 and 1944.

Shipments of manganese ore were made by 56 concerns in 1944 compared with 50 in 1943. However, at the close of the year production virtually ceased in the State as a result of the new Metals Reserve Company specifications. Unless the grade of ore shipped from California can be improved to meet these specifications, operators will be dependent upon a small local market.

Georgia.—Neel & Neel shipped the total quantity of manganese ore from Georgia and 56 percent of the ferruginous ore from the Aubrey mine, Bartow County, in 1944. Relatively small quantities of ferruginous ore were shipped from the New Riverside, Beardon, and White mines in Bartow County. The high-grade ore was sold to Metals Reserve Company, and the low-grade was shipped to consumers in the Birmingham district.

Michigan.—Pickands, Mather & Co. shipped manganiferous iron ore from the Bengal mine, Iron County, Menominee range. The ore averaged (natural) 8.60 percent Mn, 40.69 percent Fe, 5.64 percent SiO_2 , 0.364 percent P, and 7.39 percent moisture.

Minnesota.—Ferruginous manganese ore averaging (natural) 13.976 percent Mn was shipped from the Louise and Merritt mines in Crow Wing County. Manganiferous iron ore was shipped from 4 mines on the Cuyuna range and 2 on the Mesabi during the year.

Montana.—Manganese ore in Montana comes from the Philipsburg district in Granite County and the Butte district in Silver Bow County. Since 1941, when operations were begun, the nodulizing works of the Anaconda Copper Mining Co. has been the Nation's leading producer of high-grade manganese-bearing raw material. During 1944 this operation produced 53 percent of the total United States output of manganese ore. The nodules averaged (natural) 60.61 percent Mn,

3.00 percent Fe, 8.19 percent SiO_2 , 0.063 percent P, and 0.015 percent moisture. The second largest producer in the United States was the nodulizing works of the Domestic Manganese & Development Co. at Butte. This operation is discussed earlier in this chapter under New Operations.

A small shipment of ferruginous ore was made from the Mohawk mine in Madison County. Other shipments were made from the Climax Lease mine and the Sharktown mine in Granite County.

Nevada.—Production of manganese ore from Nevada operations in 1944 was more than double the 1943 total. Sixty-four percent of the output came from the leaching and nodulizing plant of the Manganese Ore Co. in Clark County. The ore for this operation was obtained from the Three Kids mine and averaged (natural) 18.66 percent Mn in 1944. The remainder of the manganese-ore production came largely from the Manganese Mining Co. mine in White Pine County, the Black Rock mine in Lander County, and the Black Diablo mine in Pershing County. Small shipments were made from the Big Jim claim in Churchill County and the Sunny Day and Valley View mines in Humboldt County.

New Mexico.—The production of manganese ore from New Mexico in 1944 came from the Birchfield, National Defense, and Rock House mines in Sierra County. The ferruginous manganese ore was produced from the Boston Hill mine in Grant County.

South Carolina.—Abernathy & Kehaya shipped metallurgical ore containing (dry) 39.40 percent Mn and chemical ore containing (dry) 37.5 percent Mn from the Boykin Kelly & Dorn mines in McCormick County. H. M. Clegg shipped ferruginous ore from the Greenwood mine in Greenwood County.

Tennessee.—The Glenn Street mine in Unicoi County supplied virtually all of the manganese ore from Tennessee during 1944. Very small shipments were made from the Blackburn and Kemp Shoun mines in Johnson County. Of the ferruginous ore, 2,858 short tons came from the Embree mine in Washington County, and the balance was shipped from the Metals Reserve Company stock pile at Elizabethton.

Utah.—A small shipment of manganese ore was made from the Oxen 1 & 2 mines in Utah County. The Black Boy mine in Juab County (12,877 tons) and the Metals Reserve Company shipping from the stock pile at Joy supplied the ferruginous manganese ore in 1944.

Virginia.—The number of Virginia shippers declined from 17 in 1943 to 8 in 1944. The Dominion Manganese Corp., a new shipper, supplied 64 percent of the State total from the old Dominion mine in Augusta County. Other important producers were the Glade Mountain mine in Smyth County (4,885 short tons) and the Virginia Hardwood Lumber Co. mine in Bland County. Small operations in Bland, Campbell, and Smyth Counties contributed toward the total.

Washington.—The total production from Washington was hausmannite ore averaging (dry) 51.79 percent Mn, 1.72 percent Fe, 9.50 percent SiO_2 , and 0.05 percent P, from the Crescent mine in Clallam County.

IMPORTS OF MANGANESE ORE

Satisfactory data covering imports of battery-grade ore are not available for 1944. However, it is believed that all battery ore during

the year came from Gold Coast. Imports classified as battery ore from that country during 1944 totaled 54,941 short tons containing 31,153 tons of manganese.

Imports of ferruginous manganese ore (all from Mexico) amounted to only 38 short tons containing 12 tons of manganese. Imports for consumption of this material (all from Mexico) totaled 160 tons containing 42 tons of manganese and were valued at \$3,207.

The following table gives imports of all grades of manganese ore during 1944.

Manganese ore (35 percent or more Mn) imported into the United States, 1943-44 by countries

¹ Comprises ore received in the United States during year; part went into consumption, and remainder entered bonded warehouses.

² Comprises receipts during year for consumption and ore withdrawn from bonded warehouses during year (irrespective of time of importation).

³ Less than 1 ton.

⁴ United Kingdom of Great Britain and Northern Ireland.

CONSUMPTION AND STOCKS OF MANGANIFEROUS RAW MATERIALS

The consumption of manganese ore in 1944 increased less than 5,000 tons over the total of 1,588,323 tons consumed in 1943. Of the 1944 total, 90 percent was of foreign origin, compared with 86 percent in 1943. Industrial stocks of manganese ore on December 31, 1944, were 42 percent less than the 854,632 tons on hand at the end of 1943.

The following table shows actual tons of manganese ore (containing 35 percent or more manganese, natural) and alloys consumed during 1944 and in stock at the end of the year.

¹ Estimated none was consumed.

METALLURGICAL INDUSTRY

The steel industry in 1944, as in 1943, used an average of 13.3 pounds of manganese per short ton of steel produced. Of the 1944 consumption, 11.7 pounds were in the form of ferromanganese, 0.6 pound as spiegeleisen, 0.9 pound as silicomanganese, and 0.1 pound as manganese ore used directly. In 1943 the consumption of manganese contained in ferromanganese, spiegeleisen, and silicomanganese, and manganese ore amounted to 11.7 pounds, 0.7 pound, 0.6 pound, and 0.3 pound, respectively, per ton of steel.

The above data apply to the consumption of manganese ore in the manufacture of steel ingots and that part of steel castings manufactured by concerns that also produce steel ingots.

Open-hearth operations are the greatest users of manganese in the United States. Manganese is added to the open-hearth melt essentially as an alloying agent, a deoxidizer, and a desulfurizer. As an alloying agent, manganese has no marked effect on tensile strength of steel when below 0.3 or 0.4 percent because other substances, especially iron oxide, mask the effect. Consequently, if the beneficial effects of manganese upon tensile strength are desired, it is important to maintain as much manganese as possible in the bath, as the amount to be added during recarburizing is reduced in direct proportion to the weight of the residual manganese.

Manganese is added to the bath near the end of the heat in the form of a recarburizer. Some years ago the principal purpose of this addition was to raise the carbon content to a desired level. However, at present its most important purpose is to rid the bath of as much oxygen as possible. The recarburizer contains manganese, silicon, and carbon. It often consists of ferromanganese and ferrosilicon but has been replaced to some extent by silicomanganese, which is considered superior under certain conditions because the oxides formed from this alloy coalesce and separate more easily from the steel, eliminating the so-called oxidized inclusions before the steel freezes. Unless manganese and silicon are added in quantities above that necessary theoretically to satisfy the oxidizing reactions, the effect will be incomplete. Consequently, the recarburizer is so calculated that about 0.50 percent manganese and 0.10 percent silicon are left in the open-hearth steel at the end of the heat.

Sulfur is eliminated from steel mainly through the formation of manganese sulfide, which separates from solution in the liquid bath and slowly rises to the surface. When in contact with a basic slag the manganese sulfide will react to form calcium sulfide, which remains in the slag. As lime may be added only to basic furnaces, acid furnaces will not remove sulfur. Manganese in pig iron is desirable in removing sulfur and should be relatively high.

Ferromanganese.—The domestic output of ferromanganese increased only slightly over 1943—from 702,484 tons in 1943 to 702,632 tons in 1944. Ferromanganese was produced at the following plants during the year:

Bethlehem Steel Co., Johnstown and Bethlehem, Pa.
E. J. Lavino & Co., Reusens, Va. and Sheridan, Va.
Sloss-Sheffield Steel & Iron Co., North Birmingham, Ala.
Tennessee Products Corp., Rockdale and Rockwood, Ala.
U. S. Steel Corp., various plants.
Electro-Metallurgical Co., various plants.

Ten percent of the total manganese ore used in 1944 for the production of ferromanganese was of domestic origin compared with 14 percent in 1943. Based on the relative manganese content of foreign and domestic ore, 12 percent of the ferromanganese was made from domestic ore in 1944. The recovery of manganese from ore in making ferromanganese was 85.76 percent in 1944 compared with 85.26 percent in 1943.

¹ Steel, vol. 116, Jan. 1, 1945.

Spiegeleisen.—Production of spiegeleisen increased 11 percent over 1943; shipments increased 3 percent in quantity and 0.5 percent in value.

Spiegeleisen produced and shipped in the United States, 1940-44

Year	Pro-duced (short tons)	Shipped from furnaces		Year	Pro-duced (short tons)	Shipped from furnaces	
		Short tons	Value			Short tons	Value
1940.....	114,119	119,512	\$3,487,565	1943.....	149,036	150,136	\$4,827,954
1941.....	177,915	181,777	5,793,481	1944.....	165,530	155,325	4,851,490
1942.....	186,026	186,163	5,931,728				

Spiegeleisen was manufactured at the following plants during 1944:

Inland Steel Co., East Chicago, Ind.
New Jersey Zinc Co., Palmerton, Pa.
U. S. Steel Corp., various plants.

In addition to the foregoing plants, shipments were made by E. J. Lavino & Co., Reusens, Va., and Sheridan, Pa., and Sloss-Sheffield Steel Iron Co., North Birmingham, Ala.

Most of the spiegeleisen produced in the United States is made from domestic raw materials. However, 534 tons of Portuguese West African ore containing (natural) 49.60 percent manganese were consumed in the production of spiegeleisen during 1944. Imports of spiegeleisen for consumption in 1944 increased 16 percent in quantity and 9 percent in value over 1943. The total supply came from Canada.

Spiegeleisen imported for consumption in the United States, 1940-44

Year	Short tons	Value	Year	Short tons	Value
1940.....	17,455	\$638,732	1943.....	3,254	\$140,247
1941.....	4,741	215,108	1944.....	3,761	153,032
1942.....	1,990	95,853			

The prices of spiegeleisen (20-percent) at producers' furnaces, as quoted by Steel, remained constant at \$36.00 per long ton (32.14 per short ton) during 1944.

Manganiferous pig iron.—Pig-iron blast furnaces used 24,462 tons of manganiferous zinc residuum and a total of 1,357,408 tons of domestic ore containing over 5 percent (natural) manganese in 1944; of this ore, none contained 35 percent or more manganese, 108,915 tons contained 10-35 percent manganese, and 1,248,493 tons contained 5-10 percent manganese. In addition, 19,871 tons of foreign ore containing over 35 percent manganese and 1,844 tons containing 10-35 percent manganese were used during the year.

BATTERY AND MISCELLANEOUS INDUSTRIES

Manganese ore for battery use should have a high content of available oxygen with minimum iron and be relatively free from such metals as arsenic, copper, nickel, or cobalt, which are electronegative to zinc. Chemical ore has a wide range in analyses and a great many uses; the bulk is used in photography (in the manufacture of hydroquinone), in fertilizers, and in coloring agents for paints and ceramics.

Data covering production, imports, consumption, and stocks of such ores are given elsewhere in this chapter.

PRICES

Prices of manganese ore (except battery and chemical ore) are upon a unit basis, the unit being 1 percent of a long ton or 22.4 pounds of contained manganese. Prices of chemical ore are quoted upon a per-ton basis, with a minimum requirement of manganese dioxide. A duty of one-half cent per pound of contained manganese is imposed on all imported manganese ore except that from Cuba and the Philippine Islands, which enters duty free.

Ceiling prices on manganese ore were unchanged throughout 1944. However, on May 15 the Metals Reserve Company prices were lowered 5 cents per long-ton unit in the Eastern (Norfolk, Baltimore,

Philadelphia, and New York) and Western (Fontana, Pueblo, and Provo) areas—from 90 cents and 96 cents to 85 cents and 91 cents, respectively. The old price of 85 cents at Mobile and New Orleans remained unchanged.

The average mine value reported for ore containing 35 percent or more manganese during 1944 was 76 cents per long-ton unit compared with 73 cents in 1943. Quotations on imported ore in the following table are from Engineering and Mining Journal.

Domestic prices of imported metallurgical manganese ore in 1944, in cents per long ton unit

[C. i. f. North Atlantic ports, cargo lots, exclusive of duty]

	Begin- ning of year	End of year		Begin- ning of year	End of year
Brazilian, 48 percent Mn.....	\$0.788	\$0.738	Cuban (not dutiable), 48 per- cent Mn.....	\$0.900	\$0.850
Chilean, 48 percent Mn.....	.788	.738	Indian:		
South African, 48 percent Mn.....	.788	.738	50 percent Mn.....	.798	.748
Cuban (not dutiable), 51 per- cent Mn.....	.915	.865	48 percent Mn.....	.788	.738

According to Engineering and Mining Journal, prices for chemical ores per long ton in carlots at the end of 1944 were as follows: Brazilian or Cuban, 80 percent MnO_2 , \$55.00; Javan or Caucasian, 85 percent minimum, \$70 to \$75; domestic, 70 to 72 percent, \$45 to \$50 f. o. b. mines.

¹ In addition to countries listed Belgium produces manganese ore, but data of output are not available. Czechoslovakia reports a production of manganese ore, but as it has been ascertained that the product so reported averages less than 30 percent Mn and therefore would be considered ferruginous manganese ore under the classification used in this report, the output has not been included in the table.

U. S. S. R.

The Nikopol manganese district was retaken by Soviet forces on February 8, 1944, after 2½ years of German occupation. However, demolition by the enemy and other results of the war prevented any important production from that district during 1944, and output of the U. S. S. R., normally the World's largest producer, was the lowest in 20 years. The manganese ore of the Soviet Union occurs largely in the Republics of Georgia and Ukraine. A discussion of the two main districts follows:

Chiaturi.—This district is situated in the Republic of Georgia on the southern slope of the Caucasus Mountains near Chiaturi and normally supplies most of the Soviet Union's export ore.

The manganiferous beds, which are horizontal and continuous, vary in thickness from 4 to 9 feet, and the ore itself is 3 to 5 feet thick. Sandstone composes both the roof and the floor. The method of working is a form of longwall retreating, galleries being driven in the ore beds and ore being extracted on either side up to the pillars which are left to protect the entry. Since they are practically horizontal, galleries begin on one side of the ridge and pass out at the other almost

at the same level; some of them attain a length of 4,000 feet. The mines are usually dry, and only light explosives are used, where necessary, in breaking down the ore. Generally speaking, the richest ore beds are found in the central field, those in the outside diminishing both in quality and quantity. The ores are treated at plants erected in the valleys and transported by aerial ropeway to storage bins at the Chiaturi rail sidings.

The ore is composed of pyrolusite with some psilomelane and wad. The average manganese content of the crude ore is about 40 percent, and about $2\frac{1}{2}$ or 3 tons of crude ore produce 1 ton of concentrate. The concentrates produced have a manganese content ranging from 44 to 52 percent and are produced by log-washing and jigging. The ore shipped is so high in fines that much of it is unsuitable for use in blast furnaces unless mixed with other ores or sintered.

During the German occupation of the Ukraine Republic, the U. S. S. R. depended on Georgian ores for its own requirements, and none was available for export. United States imports of Chiaturi manganese ore ceased in 1940.

Nikopol.—This district is on the east bank of the Dnieper River, below the town of Zaporozhe in the Ukraine and about 100 miles from the Gulf of Odessa. The field is divided into an eastern and a western section by a zone of crystalline rocks barren of ore. The western section covers an area about 12 miles long and 6 miles wide. In the eastern section the limits of five ore bodies have been defined, all of similar type and each covering an area of a few square miles.

The ore bed is horizontal and varies in thickness from 3 to $11\frac{1}{2}$ feet, averaging $6\frac{1}{2}$ feet. As at Chiaturi, it consists of clay mixed with powdered manganese ore, enriched by oölites and nodules of pyrolusite and psilomelane varying in diameter from a fraction of an inch to 19 inches. Other ore minerals present are wad, limonite, and hematite. The mines are worked at depths of 50 to 280 feet by underground methods similar to those at Chiaturi.

The ore as mined runs from 20 to 36 percent manganese and averages 30 percent. Where possible, the ore is hand-sorted before going to the concentrating plant, where it is crushed, washed, and concentrated with jigs and tables or by flotation. About 3 tons of crude ore are required to make 1 ton of concentrate running from 40 to 50 percent manganese.

Whereas Chiaturi normally supplies most of the ore for export, Nikopol supplies domestic demands. Normal production from Nikopol is over a million tons per year. In 1900 N. A. Sokolov estimated the ore reserves of Nikopol district at 50,000,000 tons; in 1931 P. I. Vasilenko estimated a total of 398,000,000 tons.

CHROMITE

Metals Reserve Company	604	World production	612

SUMMARY

The year 1944 was featured by decreases in the domestic production, importation, and consumption of chromite. Exports were at the lowest level since their separate reporting was begun in July 1941. The net effect of these changes was an increase of 44,551 tons in the total apparent stocks of chromite, although the stocks in the hands of industry decreased during the year by 67,100 short tons to 303,200 tons.

POSTWAR OUTLOOK

There seems to be no current reason to revise the estimate in Minerals Yearbook, 1943, that in the postwar period a higher rate of chromite consumption is indicated than in the prewar years.¹ The same imponderable factors that made the 1943 estimate indeterminate remain in 1944. The probability is, however, that postponed civilian demand has increased. The needs of the European countries for the rehabilitation of war-wrecked industries unquestionably have increased, but whether buying power will be forthcoming to translate these needs into consumption remains problematical. It is assured that a market for the tooling of new plant installations (particularly in the case of U. S. S. R.) will be a large factor contributing to increased requirements for chrome-containing steels. Probably the largest demand will manifest itself in the engineering,

¹ Minerals Yearbook, 1943, p. 625.

corrosion-resisting, and heat-resisting alloy steels and other chrome alloys. The effectiveness of these requirements will depend on postwar economic conditions.

In prewar years producers of machine tools, chemical equipment, road-building machinery, and other items were large consumers of chromium. Much similar equipment has been manufactured for war use. It is difficult to estimate, however, the role of this war-purpose equipment in the postwar economy. It seems safe to say that a large amount of machinery of standard design, though manufactured as a war necessity, can find a place in industry with little or no alteration. However, if war-purpose plants are held in "stand-by condition" for any considerable period the effect of this machinery on the immediate postwar market will be less than might be expected.

Under any circumstances large volumes of scrap (both war scrap and unused war materials) are to be expected. If scrap is remelted in the electric furnace a high recovery of chromium will result,² whereas if it is remelted in the open hearth much of the chromium will be oxidized and lost in the slag.

Indications of the character of domestic production compared with the grade of imported ore are given under the section on actions by Metals Reserve Company. There is no reason to expect an increase in the consumption of low-grade domestic production unless and until some commercially feasible method of treatment is established. Twice in the last 30 years domestic production has mushroomed to unprecedented heights in wartime only to decrease rapidly when hostilities cease.

Chromite shipped from mines in the United States, 1913-19 and 1938-44

Year	Short tons	Year	Short tons
1913.....	286	1938.....	909
1914.....	662	1939.....	4,048
1915.....	3,675	1940.....	2,982
1916.....	52,680	1941.....	14,259
1917.....	48,973	1942.....	112,876
1918.....	92,322	1943.....	160,120
1919.....	5,688	1944.....	45,629

Of the domestic chromite delivered to Metals Reserve Company since its purchasing program was begun on November 1, 1941, 269,597 short tons remained in its hands on January 1, 1945, out of 318,427 tons purchased.

GOVERNMENT ACTIONS

Stock-pile legislation.—On October 3, 1944, the Surplus Property Act of 1944 (Public, 457, 78th Congress) was approved by the President. Section 22 of this act, which covers the stock-piling provisions, is discussed in the chapter entitled "Review of the Mineral Industries in 1944" in part I of this volume.

One direct result of this legislation will be to prevent the dumping of Government stocks of surplus chromite on the market at the end of hostilities, provided the stocks are declared surplus before January 2, 1946. The law permits the processing of materials into the form "best-suited to the common defense."

² Iron Age, Electric Furnace Operators Debate Production Problems: Vol. 154, No. 16, Oct. 19, 1944, pp. 66-73.

The Army and Navy Munitions Board has submitted to Congress, in accordance with the Surplus Property Act of 1944, a report recommending—with respect to chromite—the transfer of surplus Government-owned metallurgical and refractory grades of ores and concentrates to stock pile and further acquisition of these grades; and the transfer but not the additional purchase of Government-held material of chemical grade. For security reasons, no quantitative recommendations are included in the published document.

War Production Board.—During 1944 an extremely difficult shipping situation³ threatened the flow of adequate imports of chromite, notably from Southern Rhodesia and the Transvaal. As a result of this condition, the Bureau of Mines, in cooperation with the War Production Board, early in 1945 revised its questionnaire covering the production of chromium products and the consumption of chromite so that it would include data on the consumption of Rhodesian, Turkish, and Russian materials as distinct from all other types and would also classify consumption as lumpy ore, friable fines, or concentrates.

On January 21, 1944, the War Production Board issued Allocation Order M-370 placing under complete allocation chromium oxide green and zinc chromate, while limiting the purchase of the other chrome pigments.⁴

On November 2, 1944, Order M-18-b was replaced by General Allocation Order M-300, Schedule 62. This order covers the allocation of "Primary Chromium Chemicals" which are defined by the order as "sodium bichromate, potassium bichromate, sodium chromate, potassium chromate, ammonium bichromate, chromic acid, and all chromium tanning compounds." Although some minor changes were made, the order substantially continued Order M-18-b. There was no time lapse in the continuity of the two orders.

On January 12, 1944, General Limitation Order L-223 was revoked, removing restrictions on the distribution, sale, and use of hard facing materials. This order affected alloys containing cobalt, chromium tungsten, molybdenum, vanadium, or secondary aluminum. This order had been in effect since December 2, 1942.⁵

On January 15, 1944, Issue 11 of the Material Substitution and Supply List (Conservation Division, W. P. B.), placed ferrochromium in group III (materials readily available for essential uses).

Direction 2 to General Preference Order M-18-a, which became effective on June 28, 1944, prohibited the melting of chromium to make nickel-chrome resistance wire or the delivery of such wire for unauthorized uses.

Office of Price Administration.—Amendment 4 to M. P. R. 258, effective April 15, 1944, exempted from price control sales or deliveries of chrome ores in quantities of 500 pounds or less.

Amendment 5 to M. P. R. 258 was issued on October 2 and became effective on October 7, 1944. This amendment provided for a discount of 7½ percent (but not to exceed \$3.50 a long ton) on concentrates and unscreened ores having certain undesirable physical and chemical properties, specifically to Transvaal B, Russian, and Philippine ores and concentrates.

Metals Reserve Company.—On September 1, 1944, Metals Reserve Company issued schedules covering the purchase (contract or small-

lot) of domestic chromite during the period from January 1 to June 30, 1945.

The price schedules in effect in 1944 and during the first 6 months of 1945 are given in the accompanying table.

Metals Reserve Company price schedules of chromite in effect in 1944 and January 1 to June 30, 1945

	1944	Jan. 1-June 30, 1945, inclusive
Base price for ore 48 percent Cr_2O_3 and Cr: Fe ratio 3: 1..... per long ton..	\$52.80	\$52.80
Minimum acceptable analysis:		
Cr_2O_3 percent minimum.....	35	42
Cr: Fe ratio..... minimum.....	$1\frac{1}{2}$:1	2:1
SiO_2 percent maximum.....		10
Premiums:		
For each 1 percent of Cr_2O_3 in excess of 48 percent..... per long ton.....	\$1.10	\$1.10
For each 0.1 in ratio above 3: 1 not to exceed $3\frac{1}{2}$: 1..... do.....	1.50	1.50
Penalties:		
For each 1 percent Cr_2O_3 below 48 percent down to limiting acceptable analysis..... do.....	1.10	1.10
For each 0.1 in ratio below 3: 1 down to 2: 1..... do.....	1.50	1.50
For ratio below 2: 1 down to $1\frac{1}{2}$: 1..... do.....	15.00	

¹ Plus \$1 per ton for each decrease of 0.1 below 2: 1.

On December 31, 1944, Metals Reserve Company had in its possession 834,564 short tons of chromite held in stock pile at purchase depots and by agencies. The composition of these stocks, by Cr_2O_3 content and by domestic or foreign origin, is given in the accompanying table.

Metals Reserve Company stocks of chromite in storage in the United States including materials available for allocation and held at purchase depots and by agents, on Dec. 31, 1944, in short tons

	Cr_2O_3 , percent					Total tonnage
	Over 48.00	45.00 to 47.99	42.00 to 44.99	35.00 to 41.99	Less than 35.00	
Ore at M. R. C. stock piles (exclusive of purchase depots and agencies).						
Metallurgical grade:						
Imported.....	271,011	25,231	3,400	9,860		309,502

Domestic.....						
				95,038	146,834	241,872
Domestic ore at purchase depots and agencies (unclassified as to use grade).						
Purchase depots:						
Ore.....	2,718	7,530	2,224	31,511		43,983
Concentrates.....	42	207	784	1,036		2,069
Agencies:						
Primary concentrates.....					59,983	59,983
	2,760	7,737	3,008	32,547	59,983	106,035
Total imported.....	274,067	25,439	13,729	104,898	146,834	564,967
Total domestic.....	2,760	33,349	48,957	124,548	59,983	269,597
Grand total.....	276,827	58,788	62,686	229,446	206,817	834,564

Total Metals Reserve Company sales of domestic chromite during 1944 amounted to 14,164 short tons. The tenor of this domestic ore and concentrates sold was as follows:

Cr ₂ O ₃ content (percent):	Short tons sold
Over 48.00.....	7,710
45.00 to 47.99.....	4,743
42.00 to 44.99.....	1,225
35.00 to 41.99.....	486
	14,164

Total sales of chromite by Metals Reserve Company are shown in the accompanying table.

Sales of domestic and imported chromite by Metals Reserve Company, 1941-44, in short tons

Year	Foreign	Domestic	Total
1941.....	9,697		9,697
1942.....	105,838	14,598	120,436
1943.....	158,975	20,068	179,043
1944.....	319,205	14,164	333,369
	593,715	48,830	642,545

MARKET AND PRICES

During 1944 Metals Reserve Company has continued to be the major purchaser of domestic chromite, as it has been since November 1941.

Maximum Price Regulation 258, covering commercial transactions noted under Government Actions, was in effect during the year. This schedule of prices will be found in the Minerals Yearbook, 1942, p. 633.

Prices quoted by E. & M. J. Metal and Mineral Markets for various grades of chromite remained unchanged during the year.

E. & M. J. Metal and Mineral Markets price quotations for various grades of chromite in 1944, per long ton

	Cr ₂ O ₃ , percent	Cr:Fe ratio	Price

UNITED STATES

PRODUCTION IN 1944

The domestic production of chromite in 1944, in terms of shipments from mines, fell to a figure of 45,629 short tons, the lowest since 1941. California furnished 76 percent of the total output, Oregon 17 percent, and Alaska and Montana the remainder.

Chromite production (shipments) in the United States, 1941-44, by States, in short tons, and number of producers in 1944

State	1941	1942	1943	1944				Total

1,000 to 5,000 tons	6,058	4,110		10,168
500 to 1,000 tons	918	2,670		3,588
Less than 500 tons	2,867	5,035	278	8,180

*Alaska.*⁶—The Chrome Queen Mining Co. resumed operations in May 1944 at its Chrome Queen mine on Kenai Peninsula near Seldovia, after closing during the winter months on account of weather conditions. Shipments for the year totaled 1,845 short tons, averaging 43 percent Cr₂O₃, with a chrome : iron ratio of 2.8 : 1. Operations at the mine ceased with the closing of the Metals Reserve Company purchasing depot at Jakolof Bay on August 15, 1944.

*California.*⁷ ⁸—Although chromite was shipped from 22 counties in California in 1944, most of it came from properties in the following counties: Del Norte, Eldorado, Fresno, Glenn, Humboldt, Placer, San Luis Obispo, Shasta, Siskiyou, and Tehama.

⁶ Julihn, C. E., and Moon, Lowell B., Summary of Bureau of Mines Exploration Projects on Deposits of Raw Material Resources for Steel Production: Bureau of Mines Rept. of Investigation 3801, 1945, p. 4.

⁷ Rynearson, G. A., and Wells F. G., Geology of the Grey Eagle and Some Nearby Chromite Deposits in Glenn County, Calif.: Geol. Survey Bull. 945-A, 1944, 22 pp.

⁸ Smith, Clay T. and Griggs, Allan B., Chromite Deposits Near San Luis Obispo, San Luis Obispo County, Calif.: Geol. Survey Bull. 945-B, 1944, pp. 23-44.

The Castro group of mines in San Luis Obispo County, operated by the Castro Chrome Associates, was the largest producer of chromite in California. The output in 1944—of which 97 percent was in the form of concentrates—totaled 10,897 short tons. The concentrates averaged 43 percent Cr_2O_3 with, a chrome : iron ratio of 2.6 : 1. The mill, located at Goldtree Siding, suspended operations late in 1944.

The second-largest producer was the French Hill mine,⁹ operated by Tyson Chrome Mines, Ltd. The mine is about 22 miles northeast of Crescent City in Del Norte County. Shipments from this property totaled 6,906 short tons averaging 43 percent Cr_2O_3 and 12 percent iron.

Shipments of high-grade ore from the High Plateau mine in Del Norte County continued in 1944. The mine was owned and operated by Eugene R. and Beatrice Brown.

Shipments of concentrates in 1944 from the Grey Eagle property in Glenn County, which for 2 successive years was the largest chromite producer in California, dropped to 3,528 short tons, averaging 47 percent Cr_2O_3 and 15 percent iron. Operations by the Rustless Mining Corp. ceased early in 1944 because of exhaustion of commercial ores.

Montana.—The Silver Star Chrome Co., operating the Mohawk mine and mill in Madison County, was the only Montana producer in 1944. Production amounted to 1,251 short tons, averaging 37 percent Cr_2O_3 . The mine and mill closed in May 1944 upon cancellation of Government contract.

Oregon.—Chromite was shipped in 1944 from mines in Curry, Grant, Jackson, and Josephine Counties.

The largest producer was the Oregon Chrome mine in Josephine County, owned by the Oregon Chrome Mines, Inc., and leased to William S. Robertson. Total production amounted to 5,890 short tons averaging 45 percent Cr_2O_3 and 11 percent iron. In addition to maintaining regular production, Robertson conducted a development program.¹⁰

EXPLORATION AND DEVELOPMENT

In March 1945 the Bureau of Mines issued Report of Investigations 3801, covering the Bureau's exploration work on a number of strategic minerals, including chromium, carried out during the fiscal years 1940-44. Individual projects examined were:

California: Seiad Creek, Siskiyou County; Little Castle Creek, Shasta County; Grey Eagle, Glenn County; San Luis Obispo, San Luis Obispo County; McGuffey Creek Chromite, Siskiyou County; Coggin Property, Siskiyou County; McCormick Property, Tuolumne County; French Hill, Del Norte County.

Georgia: Louise Chromite, Troup County.

Montana: Benbow-Mouat Properties, Stillwater County; Gish Area of Stillwater Complex, Sweetgrass County; West Fork Area, Sweetgrass County.

Oregon: John Day Area, Grant County; Sourdough Area, Curry County; Oregon Beach Sands, Coos County.

Pennsylvania: Oxford Property, Chester and Lancaster Counties.

Wyoming: Casper Mountain, Natrona County.

Alaska: Red Mountain, Kenai Peninsula; Knik Valley Deposits, Southwestern Alaska.

⁹ Julihn, C. E., and Moon, Lowell B., Summary of Bureau of Mines Exploration Projects on Deposits of Raw Material Resources for Steel Production: Bureau of Mines Rept. of Investigations 3801, 1945, p. 3.

¹⁰ Mining Journal (Arizona), vol. 28, No. 9, Sept. 30, 1944, p. 30.

The Geological Survey continued its program of mapping the principal active chromite mines, which include, in California, the McCormick (Tuolumne County), French Hill (Del Norte County), and High Plateau (Del Norte County) mines and, in Oregon, the Oregon Chrome (Josephine County) mine. The work on the McCormick and French Hill mines was done in conjunction with the Bureau of Mines.

The Geological Survey program in Cuba was continued in cooperation with the Foreign Economic Administration. Geologic mapping in the Camaguey district was completed, with results that are encouraging for future geophysical prospecting. Information on the mines in Oriente Province was kept current, with mapping of the larger mines in the Moa and Mayari districts and some reconnaissance mapping.

No extensive investigations of chromite deposits in Alaska were made by the Geological Survey in 1944. Several of the chromite deposits at Red Mountain, Kenai Peninsula, were briefly examined by the Geological Survey in connection with a Bureau of Mines exploratory project in that area.

During the year reports were published on the Grey Eagle and nearby deposits in Glenn County, Calif.,¹¹ and deposits in San Luis Obispo County, Calif.¹²

HISTORICAL SURVEY OF SUPPLY

A survey of the relative growth of total supply, of domestic production, and of the relation of domestic production to total supply for 5-year periods from 1891 to 1943 is given on page 632 of Minerals Yearbook, 1943. The details, in tonnages, for 1940-44 are given in the accompanying table.

Total supply, imports for consumption, domestic production, and consumption of chromite, 1940-44, in short tons

	1940	1941	1942	1943	1944
Total supply.....	739,594	1,129,551	1,094,483	1,088,696	894,019
Imports for consumption.....	736,612	1,115,292	981,607	928,576	848,390
Domestic production.....	2,982	14,259	112,876	160,120	45,629
Consumption by industry.....	562,915	800,290	891,952	964,600	848,449

CONSUMPTION

Consumption of chromite declined to 848,449 short tons in 1944 from the all time high of 964,600 tons in 1943, a decrease of 12 percent.

As was to be expected, the pressure of wartime demand resulted in a decrease in the tenor of ore consumed; with the subsequent decline in consumption, the demand for higher-content ores has become operative. The accompanying table shows consumption by primary consumer groups and the tenor of ore for the period 1940-44.

¹¹ Rynearson, G. A., and Wells, F. G., *Geology of the Grey Eagle and Some Nearby Chromite Deposits in Glenn County, Calif.*: Geol. Survey Bull. 945-A, 1944, pp. 1-22.

¹² Smith, Clay T., and Griggs, Allan B., *Chromite Deposits Near San Luis Obispo, San Luis Obispo County, Calif.*: Geol. Survey Bull. 945-B, 1944, pp. 23-44.

Consumption of chromite and tenor of ore used by primary consumer groups in the United States, 1940-44, in short tons

Year	Total chromite consumed		Tenor of ore (percent Cr_2O_3)		
	Gross weight (short tons)	Average tenor (percent Cr_2O_3)	Metallurgical	Refractory	Chemical

During 1944, 14,164 short tons of domestic ore were sold to industry by Metals Reserve Company.

Metallurgical chromite is consumed by the steel industry through two channels—as ferrochromium and as a direct addition to the steel bath. In 1944, 94.1 percent of this grade of ore was consumed in the form of ferrochromium and 5.9 percent as direct additions to the steel bath.

During the war years the American Iron and Steel Institute reports the production of alloy steel as follows: 1941—8,206,129 short tons; 1942—11,526,374; 1943—13,149,818; 1944—10,633,086. The consumption of ferrochromium roughly parallels the production of alloy steel.

A number of articles have appeared in the technical press describing cast-alloy tools containing chromium, which fall in the range between the high-speed-steel types and the sintered carbide alloys. Although this use for chromium metal may not offer a large outlet, it is an interesting technical development.

The consumption of chemical-grade chromite in 1944 increased 0.8 percent over the 1943 figure. During the year much difficulty was experienced in obtaining the preferred grades of Rhodesian and Transvaal chromite because shipping could not be diverted from other services for its movement. Determined efforts were made by the manufacturers of chrome chemicals to use both low-content domestic ores (on an experimental basis) and high-grade Russian material (plant scale). Reports as to the success of these experiments have been conflicting, but it appears that the difficulties are being overcome. The year 1944 has been one of largely increased demands for chrome chemicals, mostly military, and the manufacturers have faced the problem of keeping up the production with the best immediately available ores. Under these conditions neither badly needed manpower nor plant facilities could be diverted to the long time problems of utilization of unfamiliar materials.

Chrome chemicals are used for the following purposes: Tanning of upper leather for combat boots and other military footwear, as well as for civilian shoes; production of camouflage pigments, priming pigments for military aircraft and for Navy and maritime vessels; processing of textiles almost entirely for military needs; treatment of brass for ammunition; plating and anodizing of aircraft parts and frames; manufacture of a number of chemicals, most of which are subject to allocation or directive control; manufacture of pure metallic chromium for special nonferrous alloys used in aircraft and in cutting

tools; production of catalysts used in gasoline and synthetic rubber manufacture; and a number of other items of lesser importance.

The consumption of refractory-grade chromite in 1944 decreased 6.4 percent from the tonnage consumed in 1943.

It is to be hoped that reconquest of the Philippine Islands will permit operation of the chromite mines there and make available the excellent Masinloc refractory ore. During the Japanese control of the islands, dependence for refractory-grade ore has been largely upon South African and Cuban sources.

During the last 5 or 6 years a great deal of work has been done on the development of chrome-magnesia and magnesia-chrome refractories, and it is reported that much brick of these compositions has gone into commercial use.¹³

IMPORTS AND EXPORTS¹⁴

Imports of chromite in 1944 declined for the third successive year from the high of 1941. A total of 848,390 short tons of all grades was a decline of 9 percent from 1943, 14 percent from 1942, and 24 percent from 1941.

Chromite imported for consumption in the United States, 1940-44, by countries

² Listed as French Oceania by U. S. Department of Commerce.

³ Austin, Chester R., *Refractories Keep Pace With Industrial Progress: Brick and Clay Record*, vol. 104, No. 1, January 1944, pp. 39-44.

⁴ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

In 1944 the only imports of ferrochromium were from Canada and amounted to 113 short tons (79 short tons chromium content) containing 3 percent or more of carbon. There were no imports of low-carbon ferrochromium, chromium metal, chromic acid, and sodium or potassium dichromate.

Exports of chromite amounted to 1,019 short tons, of which 540 went to Canada, 410 to Brazil, and the balance to Mexico and Union of South Africa.

Exports of ferrochromium were 532 short tons, of which U. S. S. R. received the larger part. Exports of chromium metal were 37 tons, mostly to Canada. During the year 577 short tons of chrome pigments and 188 tons of chromium chemicals were exported.

WORLD PRODUCTION

World production of chromite, 1939-44, by countries, in metric tons

⁴ January to June, inclusive.

⁵ Fiscal year ended March 20 of year stated.

⁶ Estimate included in total.

⁷ Planned production.

⁸ May include some production in Yugoslavia.

Albania.—A recent publication ¹⁶ gives limited information concerning chromite in Albania. There are indications of deposits in the Shebenik and Martaneshi Mountains southeast of Elbasan and west of Pogradec. Fifty-seven thousand tons of chromite reported to contain 45 percent Cr₂O₃ were exported from the Kuitza area of the

¹⁶ The Albanian Master in His Home, Tirana, 1944, Printing House "Gurakuqi."

village districts near Pogradec. The exploitation was by an Italian firm.

Argentina.—In January it was proposed that a company be formed to exploit Argentine chromite deposits.¹⁶ The Review of the Bank of South America¹⁷ published an announcement by the Argentine Ministry of War that a mixed company, partly Government and partly privately owned, has been formed to exploit chrome deposits in the Province of Cordoba. The company is capitalized at 2,500,000 pesos, two-fifths to be supplied by the Department of Military Factories and the balance by a group of nine private shareholders. The Argentine Government hoped that, once plants are installed, supplies will be available to cover the country's entire needs.¹⁸

A decree issued November 15, 1944, proposed by the Ministry of War, forbids the exportation of chrome minerals in any of their forms or degrees of concentration.¹⁹

Australia.—Deposits of chrome ore at Tungamull in the Rockhampton district of Queensland have been recognized for some time,^{20 21} and it is reported that between January and May 1944, 389 tons were mined and shipped to Newcastle, New South Wales. Samples from the Elgalla workings, Tungamull lodes, assayed by a Government analyst, ran 36.2 percent Cr_2O_3 .²² In earlier years the ore has been used in the manufacture of refractories.

Belgium.—The Soc. d'Affinage de Nickel S. A. at Duffel near Antwerp began operations early in 1939 to refine imported ores, particularly nickel, chrome, and copper.²³

Brazil.—Brazil is stated²⁴ to be the largest exporter of chromite in South America. Five known deposits have been described.²⁵

Exports in recent years have been as follows: 1937, 850 tons; 1938, 900 tons; 1939, 3,500 tons; 1940, 4,600 tons; 1941, 4,400 tons.

Canada.—Canadian chromite production in the last 3 years has been as follows: 1942, 11,456 short tons worth \$343,568; 1943, 29,595 tons worth \$919,878;²⁶ and 1944, 27,720 tons worth \$761,229.²⁷

The report for 1943²⁸ states that 15 firms engaged in mining or developing chromite in 1943 and gives a list (pp. 31-32) of firms that have engaged in mining this ore.

Canadian consumption²⁹ in 1943 was 131,267 tons, an increase of 29 percent over that of 1942. Forty-eight percent of the total imports of nearly 112,210 tons came from Africa, mainly from Rhodesia; 29 percent from India; and 23 percent from the United States, mainly from Montana. Production of ferrochrome and other chrome addition agents in 1943 was about 47,000 short tons, an increase of 40 percent over that of 1942.

With the withdrawal of Government support,³⁰ a number of properties producing strategic metals that were unable to operate profitably at world prices, closed down. Among these is Chromeraïne in the Black Lake area.

During the year the operations of the Chromium Mining & Smelting Corp., Ltd., were at about 50 percent of capacity.^{31 32} Sales of Chrom-X (an exothermic mixture containing chromium oxide) in the United States were below the levels hoped for.

During 1943 Chromite, Ltd., had a good year,³³ improving its financial position, mining 50,600 tons of ore, and milling 2,000 tons from the dump. Concentrates produced amounted to 14,540 tons. A new shaft has been sunk.

During 1943 Manitoba Chromium, Ltd., a subsidiary of the Hudson Bay Mining & Smelting Co., Ltd.,³⁴ was formed to take over the Page chrome property in the Bird River area of Manitoba. An 85-ton shipment³⁵ was made to Ottawa for testing purposes. Further work is being done.

C. H. Stockwell³⁶ has published an exhaustive account of the chromite deposits of the Eastern Townships of Quebec.

China.—Although molybdenum and tungsten are found in China, no discovery of chromium³⁷ has been reported.

Colombia.—A small company (Industrial de Cromo Limitada) has been formed in Medellin for the treatment of locally mined chrome ore.³⁸

Cuba.—The mining of refractory chromite in 1944 was restricted to 50 percent of the 1943 figure because of large stock piles in Cuba. Exports to the United States exceeded production by 72 percent and were 6 percent larger than in 1943. The known supply in the two producing areas—Camaguey and Punta Gorda—are adequate to meet any likely export demand in 1945.

Because of an increased demand for lump metallurgical chromite of good grade, mining was renewed in the Mayari district, and the output of the principal producer more than doubled.³⁹

During the year considerable drilling, trenching, and stripping were done with a view to extending the known reserves. At least two new properties—Don Ismael and Narcisco—were opened, but it is understood that the latter was mined out some time in the summer.

Cuban production and exports of chromite in 1944, in short tons

	Production	Exports	Stocks Dec. 31, 1944
Refractory grade	191,000	330,000	142,000
Metallurgical grade.....	21,000	21,000	12,000
	212,000	351,000	154,000

Egypt.—Licenses to prospect for chromite have been issued to the Société Misr des Mines et Carrières and to Rene Kattawi of Cairo.⁴⁰

Germany.—In view of the complete absence of deposits of chromite in Germany proper, the loss of foreign sources of supply has been a staggering blow to German industry. As recorded in the Minerals Yearbook, the imports by Germany in the immediate prewar years were: 1935, 95,440 metric tons; 1936, 123,375 tons; 1937, 132,162 tons; 1938, 176,406 tons, and in the first 7 months of 1939, 136,434 tons, as compared with 78,948 tons in the corresponding months of the previous year. In 1943 Turkey is reported⁴¹ to have shipped 47,000 tons to Germany and in the first 2 months of 1944, 15,000 tons before termination of the Clodius Agreement. Another source⁴² estimates the 1943 shipments to Germany from Turkey at 30,000 tons. Shipments to Germany from all other foreign sources were subsequently cut off^{43 44 45} as a result of interruption of all rail traffic from the Balkans. It is also reported that Spanish production, substantially all of which went to Germany, increased from 500 tons in 1941 to about 4,000 tons in 1943. The relation of the Balkan sources of chrome to Germany will be described in the section on Yugoslavia.

A German broadcast monitored in England⁴⁶ mentioned that the Dr. Alexander Wacker Ges. für elektrochemische Industrie, G. m. b. H., of Munich had to reduce its ferrochrome operations owing to a shortage of chrome ore.

An excellent study of enemy (German and Japanese) ordnance materials has been published by the Battelle Memorial Institute.⁴⁷

Greece.—Early in 1944 Lord Selborne (British), Minister of Economic Warfare, stated that the Greek and Yugoslav forces had inflicted "most serious damage" on the chrome mines in those countries.⁴⁸ Greek production in 1943⁴⁹ was only 30,000 tons as against an expected 45,000 tons.

*India.*⁵⁰—The bulk of the Indian production comes from the Hassan and Mysore districts. The first discovery of this ore was made in the latter region in 1905, and mining was begun in 1907. Some of the ore contains less than 42 percent Cr_2O_3 , but there are lenses of 47- to 52-percent material. The high-grade deposits amount to about 90,000 tons. The Byrapur deposits contain a few thick lenses of over 48-percent ore. In the Mysore district the ore occurs in veins and lenses in serpentinized ultrabasic rocks. The best and largest deposits are at the Sinduvalli mine and have been worked by underground methods. These deposits have produced about 136,000 tons of ore running from 48- to 52-percent content. Further west there are deposits of 40- to 44-percent Cr_2O_3 ore. Other deposits of 30-percent ore are known (some of which can be beneficiated) but are not being mined. Chromite also occurs in Baluchistan. In 1938⁵¹ the output was 44,149 tons, of which 18,214 tons were exported. The sole previous use for

the domestic consumption was for refractories. In 1944 ⁵² there was some production of dichromates.

Japan.—The large new chrome discovery reported in the 1943 Minerals Yearbook ⁵³—in the Sarugun district—is to be exploited by the Teikoku Manganese Mining Co.⁵⁴

New Caledonia.—Arrangements have been made to refinance the Chagrin Chrome Mines, Ltd.;⁵⁵ under the new arrangement, it is expected that shipments of ore to America can be made.

Palestine.—Early in 1943 chrome ore was reclassified as a separate import item exempt from import duty.⁵⁶ It had previously been scheduled in the class with "metalliferous ores and scrap not elsewhere specified," which carried a 15-percent ad valorem duty.

Philippine Islands.—A recent estimate ⁵⁷ of chromite in the Philippine Islands places the reserves of refractory-grade ore at the Masinloc mine at 10,000,000 tons, a figure that agrees closely with that quoted in the 1941 Minerals Yearbook.⁵⁸ This mine is worked by open-pit methods. At the Acoje property, in the Zambales Mountains north of Bataan, 250,000 tons of high-grade metallurgical ore are estimated to be present, plus a tonnage of low-grade ore which might be beneficiated. The Japanese are reported to have exploited the Acoje and Filipinas mines for high-grade ore but to have done nothing at Masinloc.

Portuguese East Africa.—Exports of chromite from Beira to the United States in 1944 were approximately 180,000 tons as compared with 245,000 tons in 1943.

In December the shipments were classified as 23,000 long tons of metallurgical ore and 800 tons of refractory-grade.

Rumania.—It has been reported that in 1942 the first production of chrome ore since World War I was made, amounting to 500 tons.⁵⁹ Rumanian chromite reserves have been variously reported at 1 million to 10 million tons. Evidence at hand favors the lower figure. The Germans are said to have produced 40,000 tons of ore from the Temesvar mine in 1917.

Southern Rhodesia.—The mining industry in Southern Rhodesia is subject to heavy taxation ⁶⁰ but some relief is offered to small producers where actual production can be shown. The difficult shipping situation from all South African ports has been noted elsewhere in this chapter. The paucity of published information on Southern Rhodesia is in part explained by a quotation from the 1943 edition of the Rhodesian Mining Year Book: "The publication of statistics concerning mineral production—has been discontinued in the interests of the Allied war effort."⁶¹ It is evident that the technical and trade press has been guided by the same principles.

⁶¹ American Consulate General, Johannesburg, South Africa, Consular Report 20, May 4, 1943.

Spain.—On November 13, 1944, an order was published reserving provisionally in favor of the State the chrome- and nickel-ore deposits in the Province of Málaga.⁶²

Sweden.—Late in 1944 and early in 1945 there was interest in the purchase of a small tonnage of chrome concentrates in Turkey for Swedish account. Minerals Yearbooks, 1935–38, state that Sweden is normally a purchaser of chromite and that in the period 1934–38 the yearly importations ranged between 35,000 and 72,000 metric tons.

Turkey.—A new chromite deposit has been found near Dindarzik in the neighborhood of Bigaditsch,⁶³ and another discovery is reported⁶⁴ as having been made in Southeastern Anatolia, but no more definite location is given. This latter deposit is stated to be considerably richer than those hitherto known in Anatolia. Turkish exports of chromite since 1938 have been estimated⁶⁵ as follows: 1938, 208,055 metric tons; 1939, 192,842; 1940, 110,037; 1941, 81,286; 1942, 129,307; 1943, 103,000. A large part of the Turkish deliveries to Germany was made in German-owned rolling stock, which was loaned to the Turks for this purpose.⁶⁶ A reasonable estimate of the 1944 Turkish production would slightly exceed 150,000 tons. The Guleman group of mines has been the largest and most important producer of high-grade metallurgical lump ore. The production of this group in the last 9 years has been as follows: 1936, 23,000 metric tons; 1937, 49,000; 1938, 95,000; 1939, 105,000; 1940, 92,000; 1941, 64,000; 1942, 31,000; 1943, 60,000; 1944, 67,000. An estimate of an additional 250,000 tons of low-grade ore during the same period is a reasonable one. The indicated reserve of metallurgical ore in the Guleman group is 500,000 tons, and there are indications that farther east and north there may be 1,000,000 tons more. In addition to the Guleman production, concentrates are being produced at Fethiye and also at Ces by the Tekirova Co.

U. S. S. R.—According to an article in Pravda,⁶⁷ production in the Urals has trebled since the war began. At Nizhny Tagil the expansion has been of this order of magnitude, and this heavy metallurgical center has become the Red Army's chief arsenal and workshop since the Germans overran the Ukraine, Krivoi Rog, and the Donetz Basin. The Ural Range is 2,500 miles long and is rich in iron, copper, nickel, chrome, manganese, and other important ores. Exports of chromite from the U. S. S. R. to the United States in the first half of 1944 were at the rate of 100,000 long tons a year.

Union of South Africa.—Chromite production of the Union of South Africa for the years 1941–43 was as follows: ⁶⁸ 1941, 226,886 short tons, averaging 45.83 percent Cr₂O₃; 1942, 293,386 tons averaging 45.09 percent; 1943, 108,973 tons averaging 45.20 percent.

A number of heavy chrome chemicals are being made in South Africa,⁶⁹ among them bichromates, chrome tanning salts, and chromate pigments. A satisfactory standard of quality has been attained. The South African Government hopes that this industry will be maintained after the war.

⁶⁹ Chemistry and Industry, Chemistry and Industry in South Africa: No. 34, Aug. 19, 1944, p. 302.

Venezuela.—The occurrence of chromite deposits in the basic igneous rocks of Cerro Santa Ana on the Paraguana Peninsula has been known for many years. These were thoroughly investigated a few years ago but were found to be noncommercial.⁷⁰

Yugoslavia, Bulgaria, and Macedonia.—The latest chromite-production figures ⁷¹ for Yugoslavia are 58,470 tons in 1938; 43,007 in 1939; and 71,019 in 1940. Bulgaria produced ⁷² 2,350 tons in 1937, and it is thought that the production amounted to 3,000 tons in 1940. Reserves are estimated at 50,000 tons. After the acquisition of Greek Macedonia by Bulgaria, the region became the second producing area in Europe, being exceeded only by U. S. S. R.

SUMMARY

Nickel not only continued to be a critical war material in 1944, but its supply was the least abundant of the ferrous-alloying metals. However, notwithstanding that the supply available to the United States was less than in 1943, it was adequate to meet all war demands. Consumption of primary nickel in the United States was about 4 percent less than in 1943. Proportionately less nickel was used in steel mills in 1944 than in 1943, but this decline was offset in part by increases in consumption of nickel in nonferrous alloys and other products. The continued use of NE (national emergency) steels and the recovery of nickel scrap resulted in a substantial saving in nickel in 1944.

2 Excludes "All other manufactures of nickel"; weight not recorded.

3 Excludes "Manufactures"; weight not recorded.

4 Price quoted by International Nickel Co. of Canada, Ltd., for electrolytic nickel at New York, in 2-ton minimum lots.

Imports of nickel in all forms were about 3 percent less than in 1943, which, however, was a record year. Smaller receipts from Canada were partly offset by supplies of oxide from Cuba (a new producer) and increased imports from New Caledonia.

Output of nickel in Canada in 1944 was 4 percent less than the all-time high of 1943 owing to the continued labor shortage and to the use of much inexperienced labor.

As heretofore, the domestic output of primary nickel was insignificant in 1944.

The St. Louis Smelting & Refining Co. began producing nickel commercially at its property near Fredericktown, Madison County, Mo., in July 1944. The complex ore is treated in a flotation mill, which yields a lead concentrate, a copper concentrate containing some lead, and a nickel-cobalt concentrate.

POSTWAR OUTLOOK

The postwar demand for nickel has been ably discussed in the *Engineering and Mining Journal*,¹ and the article is quoted in full in the chapter of this series for 1943.

Although data on reserves of nickel ore have not been nearly as complete since the beginning of World War II, there is enough information to give assurance of ample nickel supplies for some years to come. Fortunately for the United States, the largest high-grade reserves are situated nearby in Canada, where 85 percent of the world supply has originated in recent years. Developments elsewhere probably will supplement the Canadian supply to such an extent as to reduce the proportion of the world nickel produced in Canada in the postwar period. The USSR, by its acquisition of the Petsamo nickel mine, probably will be an important factor in future nickel production, and undoubtedly it will displace New Caledonia as the second largest producing country. Despite the war in the Pacific, New Caledonia has continued to produce nickel, although at a reduced rate because of labor and supply difficulties. After the war, New Caledonia almost certainly will again produce nickel at its prewar rate. According to Nicaro Nickel Co., the future of Cuba—where production of nickel began late in 1943—as a profitable peacetime producer will depend on several factors that cannot be fully appraised at this time. Venezuela may become a future producer of nickel. That country is reported to have large reserves of relatively high-grade nickel ore, favorably situated with regard to transportation and susceptible to cheap strip mining. The International Nickel Co. of Canada, Ltd., has an option on the Loma de Hierro deposit and is investigating its potentialities. Brazil, about which great hopes of becoming a substantial producing country were entertained, will not be a factor in the immediate postwar production period, because of remoteness of the deposits and excessive costs of power, fuel, and freight. Extensive exploration and development of reported deposits of nickel in the United States by the Bureau of Mines and private companies during the war period have not resulted in the discovery of ore bodies large or rich enough to sustain a significant domestic nickel-mining industry.

Since 1929 the base price of electrolytic nickel has been at 35 cents a pound, despite the rise in production costs. The constancy of price has been possible because one Canadian company has held a dominating position as a producer. The stable price, however, has been an important factor in developing a world market for nickel. Although Canada probably will supply less of the world production of nickel than in the past, it is believed that its dominant position will have a stabilizing effect on the world price, which is not expected to change much, if any.

PRODUCTION

Domestic production of nickel is small and comprises metals recovered from scrap-nickel anodes, nickel silver, and copper-nickel alloys (including Monel metal), and primary metal recovered in copper refining and produced from ore and as a byproduct of talc production, as listed in the following table. Domestic primary nickel

¹ *Engineering and Mining Journal*, Metals for the Alloy Steels: Vol. 145, No. 2, February 1944, p. 84.

was recovered in 1944 as a byproduct in copper refining at Baltimore, Md., Carteret, N. J., Laurel Hill, N. Y., Perth Amboy, N. J., and Tacoma, Wash. Although all the nickel recovered as a byproduct of copper refining is credited to domestic production, it appears that some of the blister copper richest in nickel is that imported into the United States for refining. Roasted nickel-cobalt concentrate containing about 19 percent nickel and 12 percent cobalt was produced at Fredericktown, Mo., in 1944. Concentrates containing 10 percent nickel and 0.7 percent cobalt were recovered as a byproduct of talc production in Vermont; however, none was shipped.

Nickel produced in the United States, 1940-44

FOREIGN TRADE ²

The nickel imported into the United States in 1944 was 3 percent less than in 1943, which however was a record year. Imports comprised chiefly metallic nickel, matte, and oxide. As heretofore, Canada was the chief source of the imports; it supplied 183,868,941 pounds of metallic nickel, 53,452,748 pounds of Monel matte (averaging 53 to 54 percent nickel and 25 percent copper), 1,198,009 pounds of roasted matte (averaging 75 percent nickel), and 3,220,615 pounds of oxide. The roasted matte and virtually all the oxide were refined to nickel, and the Monel matte was refined to Monel metal and other products at the plant of the International Nickel Co., Inc., Huntington, W. Va. About 2,100 short tons of nickel were produced at Huntington from Canadian roasted matte and oxide in 1944. During the year 670,187 pounds of electrolytic nickel were received from French Morocco; this metal originated from ore mined and refined in Canada. New Caledonia supplied 18,121,982 pounds of matte that contained 77 to 78 percent nickel; it was shipped to Huntington for refining. About 5,700 short tons of nickel were produced from New Caledonia matte in 1944. Cuba furnished 7,680,367 pounds of oxide, a relatively small amount of which was refined at Wilmington, Del. Cuba also supplied 7 pounds of ore. Venezuela supplied 56,000 pounds of ore, which was reshipped to Canada. The United Kingdom

² Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

furnished 1,566,039 pounds of metallic nickel and 28,030 pounds of oxide. Switzerland supplied 68 pounds of metallic nickel.

The nickel content of the unmanufactured nickel products imported into the United States is estimated at 236,586,000 pounds in 1944, compared with 244,983,000 pounds in 1943.

Exports of nickel comprise largely products manufactured from imported raw materials. Exports of alloys (including Monel metal) and scrap were 29 percent less in 1944 than in 1943, but exports of metallic nickel were 1 percent more. Exports of nickel salts and compounds were almost double those of 1943. The USSR (7,266,647 pounds), United Kingdom (6,665,963 pounds), and Canada (852,613 pounds) were the chief markets for nickel, Monel metal, alloys, and scrap in 1944.

Nickel (excluding residues) imported for consumption in the United States, 1942-44, by classes

Class	1942		1943		1944

¹ In addition to countries listed Finland, Japan, and Sweden produce nickel, but data of output are not available.

² Data not yet available; estimate included in total.

³ Excludes small quantity produced in British Columbia.

⁴ Fiscal year ending Mar. 20 of year stated.

⁵ Estimate.

⁶ Imports into United States.

⁷ By-product in electrolytic refining of copper. In 1941 includes also production from ore and as by-product of talc; in 1944 includes also production from ore.

Brazil.—The American Smelting & Refining Co., which had an interest in the Tocantins nickel deposit in the State of Goiaz, abandoned the project in 1944. According to the company:³

It presented a difficult metallurgical problem, but this had been solved in our research laboratory in Perth Amboy. Later, however, it was found that the process, as applied to actual Brazilian conditions, would not permit of profit. The mine has a large body of ore containing nickel in an amount that, using our process, would in more favorable localities yield a suitable profit. But the pioneer conditions due to geographical remoteness of the mine, the scarcity of labor, which would have to be imported from distant localities, and the excessive cost of power, fuel and freight, were factors whose combined effect, as finally proven, could not be successfully overcome. The Company, accordingly abandoned the project and surrendered its shares for the benefit of the Brazilian stockholders.

The nickel deposits in the State of Goiaz have been described by Pecora,⁴ who concludes as follows:

The nickel-silicate deposits near São José do Tocantins, Goiaz, Brazil, are the most promising nickel-silicate deposits that have thus far been reported in the Western Hemisphere. Most of the earlier published estimates, however, of potential reserves and tenor appear too optimistic. * * * Decisions as to metallurgical process and product to be marketed will have to be made before the cut-off grade can be established, and the potential value of the deposits determined. Roads and bridges must be repaired and constructed, sources of hydro-electric power on the upper Tocantins River must be investigated, supplies of flux and fuel must be assured, and additional prospecting must be done before a local industry can be established. The ore reserves, in the opinion of the writer, do warrant the establishment of a local industry. During the critical years of the war, high-grade ore can easily be selected for shipment, and meanwhile additional development can outline new deposits of high-grade ore. Surface mining of nickel-silicate and cobalt "pebble" ore could be begun immediately, by local laborers using hand tools; and trucks could set out a day later for the railroad at Anapolis, loaded with "pebbles" of nickel-cobalt-manganese oxide or with high-grade nickel-silicate ore.

Canada.—Virtually all the Canadian output is derived from copper-nickel ores of the Sudbury district, Ontario. Some nickel is also

³ American Smelting & Refining Co., 46th Annual Report: 1944, pp. 2-3.

⁴ Pecora, W. T., Nickel-Silicate and Associated Nickel-Cobalt-Manganese-Oxide Deposits near São José do Tocantins, Goiaz, Brazil: U. S. Geol. Survey Bull. 935-E, 1944, 305 pp.

recovered as a byproduct from silver-cobalt ores of Cobalt and other areas in northern Ontario. Two companies—International Nickel Co. of Canada, Ltd., and Falconbridge Nickel Mines, Ltd.—are the principal producers. Nickel production in Canada was 137,607 short tons in 1944, compared with 144,009 tons in 1943.

Sales of nickel in all forms by the International Nickel Co. of Canada, Ltd., derived from its own mine production, was 250,212,561 pounds, a decrease of 15,176,762 pounds from 1943.⁵ Company sales, together with the volume refined for others, totaled 285,238,333 pounds in 1944.

Chiefly as a result of increased mechanization to overcome labor shortage and to improved metallurgy, Falconbridge Nickel Mines, Ltd.,⁶ made the largest production of nickel in its history in 1944. Ore treated in 1944 totaled 830,254 short tons (807,048 tons in 1943) and comprised 475,974 tons of milling ore and 354,280 tons of smelting ore. The ore treated averaged 1.59 percent nickel in 1944 (1.62 percent in 1943). Matte produced in 1944 contained 12,049 tons of nickel (11,597 tons in 1943). Ore reserves were 12,669,500 tons averaging 1.72 percent nickel on December 31, 1944.

A relatively small amount of copper-nickel ore from outlying nickel properties was again shipped to the International Nickel Co. of Canada, Ltd.

Cuba.—Mechanical difficulties incident to efficient operation of the new nickel plant of Nicaro Nickel Co. at Lengua de Pajaro were overcome during 1944, and steady progress was made toward the goal of full production. Imports of nickel oxide from Cuba were 7,680,367 pounds in 1944, some of which was refined at Wilmington, Del. According to the Freeport Sulphur Co., of which the Nicaro Nickel Co. is a subsidiary:⁷

During 1944, steady progress was made in increasing the output and the plant is now producing nickel oxide at the rate of nearly 2,000,000 pounds (contained metal) per month. Capacity operation is scheduled to be reached within the next six months. The results of this first year of production have demonstrated the practicability of the Nicaro process for extracting nickel from low-grade ores and have established Nicaro as a new source of nickel for the United States. Whether Nicaro can be made a profitable commercial venture for peacetime depends on several factors the effect of which cannot be predicted at this time. For the time being, Nicaro Nickel Company's income from the project is limited to a small fee which it receives under its contract with Metals Reserve Co.

U. S. S. R.—By the terms of the armistice agreement entered into between the U. S. S. R. and Finland on September 19, 1944, territory including the Petsamo district was ceded by Finland to the Soviet Government, and the ownership of the nickel mines and installations passed to that Government. In a protocol to the armistice agreement, signed in Moscow on October 8, the Soviet Government has undertaken to pay \$20,000,000 in equal annual installments during the ensuing 6 years as full and final compensation to the International Nickel Co. of Canada, Ltd., and its subsidiary, the Mond Nickel Co., Ltd.

Venezuela.—The International Nickel Co. of Canada, Ltd., is reported to have taken an option on a nickel-silicate deposit near Loma de Hierro, and pitting and drilling operations have been in progress to determine its potentialities. A small quantity of ore was shipped to Canada in 1944.

SUMMARY

The United Nations did not lack supplies of cobalt in 1944. Indeed, with the output of Finland available, the United Nations control virtually the entire world cobalt supply, except that of Burma. On the other hand, with Germany's loss of cobalt production from French Morocco in 1943 and Finland in 1944, its remaining current source of supply was limited to a small domestic output. Presumably, Japan was in a more favorable position than Germany with respect to cobalt because of a small domestic output and the Burmese production. However, Burmese speiss, which is obtained by smelting lead ore, is difficult to refine.

In the United States, despite the fact that cobalt was free from allocation and that imports were 32 percent less than in 1943, available supplies were more than adequate for requirements in 1944. Because of the favorable supply position it was not necessary to process available stocks of French Moroccan ore. Notwithstanding production from the newly opened property at Fredericktown, Mo., domestic output of cobalt was only 13 percent greater than in 1943.

Consumption of cobalt ore, alloy, concentrate, and speiss by refiners or processors was about 1 percent more than in 1943, but consumption of cobalt products by industrial consumers was about 5 percent greater.

Maximum prices for cobalt metal, fines, powder, oxides, and other alloys and compounds established by the Office of Price Administration on November 2, 1943, continued in effect in 1944. The maximum price for metal containing 97 percent cobalt was fixed at \$1.50 to \$1.57 a pound on contract and \$1.60 to \$1.67 on spot sales. The maximum prices for other cobalt products were the highest charged by a seller on a delivery made during January, February, or March 1942. Cobalt ores, concentrates, and crudes are exempt from the provisions of the price regulation.

Purification of cobalt precipitates containing iron and other impurities is the subject of United States patent 2,367,239. According to this patent, which is assigned to the International Nickel Co., Inc.:

The present invention relates to the purification of cobalt precipitates containing iron, cobalt, nickel and other impurities, and more particularly to the purification and recovery of high grade cobalt from precipitates obtained in the purification of electrolytes employed in the electrolytic refining of nickel. Such precipitates contain not only cobalt, but also copper, iron, arsenic, lead and nickel.

A relatively simple method of recovering cobalt from cobaltite and danaite has been devised by Forward.¹

MINE PRODUCTION AND DEVELOPMENT

Production of cobalt ore in the United States was 13 percent greater in 1944 than in 1943, but shipments were 27 percent less. The Bethlehem Steel Co., Bethlehem, Pa., was again the chief producer, but during the last quarter of 1944 it was exceeded by the St. Louis Smelting & Refining Co., Fredericktown, Mo.

Production by the Bethlehem Steel Co. was 37 percent less than in 1943. The cobalt (averaging 1.37 percent in 1944) is contained in the sulfides that accompany the magnetite mined at Cornwall, Pa. According to Horton:²

The ore, containing a little less than 1 pound of cobalt per ton, is separated magnetically to yield a magnetite concentrate and a non-magnetic reject; the latter amounts to 36 percent of the ore and contains 5.6 percent pyrite and 0.086 percent cobalt. The reject is treated by selective flotation to produce pyrite and chalcopyrite concentrates that represent 5.92 and 1.58 percent of the heads, respectively. The pyrite concentrate contains 88.7 percent pyrite and 1.39 percent cobalt and represents a recovery of 64.7 percent of the cobalt in the ore. It is shipped to the Davidson Chemical Co. at Baltimore, where it is roasted and the SO₂ used to make sulfuric acid. The calcine is shipped to the Pyrites Co. at Wilmington, Del., where it is treated chemically to recover the cobalt. * * *. In addition to magnetic reject currently produced, the Bethlehem company has approximately 7,000,000 tons in dumps. This dump material is estimated to contain 0.086 percent cobalt; based on 50 percent recovery, it would yield over 5,750,000 pounds.

The St. Louis Smelting & Refining Co. began producing cobalt commercially at its property near Fredericktown, Madison County, Mo., in July 1944. The property is developed by two shafts each about 400 feet deep and a third shaft bottomed at 440 feet. The complex ore is treated in a flotation mill, which yields a lead concentrate, a copper concentrate containing some lead, and a nickel-cobalt concentrate. The roasted nickel-cobalt concentrate contains about 19 percent nickel and 12 percent cobalt; some of it was shipped to the Ferro Enamel Supply Co., Cleveland, Ohio, for recovery of separate oxide products of nickel and cobalt chemically. The Bureau of Mines is installing facilities at Rolla, Mo., to investigate the production of nickel-cobalt-iron alloys from the Fredericktown ores.

The Sullivan Mining Co., Kellogg, Idaho, recovered 65 short tons of residues, containing 5,666 pounds of cobalt, at its electrolytic zinc plant. The Eastern Magnesia Talc Co., Inc., Burlington, Vt., recovered 7 tons of concentrates, containing 100 pounds of cobalt and 1,450 pounds of nickel, as a byproduct of the froth flotation of talc. However, these companies made no shipments in 1944.

According to Rasmussen:³

Development work on its cobalt holdings in the Blackbird district, Idaho, was continued by the Howe Sound Co. The ore is marginal, requiring payment for most of its copper, gold, and cobalt to be commercial. It will be tested in the Bureau of Mines small electrolytic cobalt pilot plant, assembled at Boulder City in 1944. A paper, "A Study of Impurities in Cobalt Electrowinning," presented at the 1944 meeting of the Electrochemical Society, discusses earlier investigations of Goodsprings, Nev., stainerite ore and recent studies of the Blackbird cobaltite.

¹ Forward, F. A., and Lyle, A. G., Recovery of Cobalt, Copper, and Gold from an Arsenical Concentrate by Roasting and Leaching: Inst. of Min. and Met., Bull. 470, London, January 1945, pp. 16-18.

² Horton, F. W., Production Problems Face Ferro-Alloy Metallurgists: Eng. and Min. Jour., vol. 145, No. 2, February 1944, (cobalt) p. 104.

³ Rasmussen, R. T. C., Interest in Ferro-Alloy Metals Centers on Plants: Eng. and Min. Jour., vol. 146, No. 2, February 1945, (cobalt) p. 131.

The cobalt-bearing manganese deposits of Alabama, Georgia, and Tennessee have been described by Pierce.⁴ According to Pierce:

Of the 101 manganese mines and prospects that were examined for appraisal of their cobalt possibilities, only a few were found to contain appreciable quantities of cobalt. It is estimated that the deposits examined contain, altogether, 7,900 tons of manganese oxides containing $\frac{3}{4}$ to $1\frac{1}{2}$ percent cobalt, or about 165,000 pounds of cobalt. Other deposits, in which the manganese oxides contain 0.2 to 0.3 percent cobalt, might supply 25,000 tons of manganese oxides containing about 140,000 pounds of cobalt.

FOREIGN TRADE⁵

Imports.—Imports of cobalt into the United States in 1944 were 32 percent less than those in 1943, which, however, was a record year. Since the invasion of Belgium, where Belgian Congo cobalt was formerly refined, Belgian Congo has been the chief source of imports into the United States; in 1944 it supplied 8,500,516 pounds in the form of an alloy containing 3,737,000 pounds of cobalt. French Morocco supplied 185,460 pounds of ore containing 28,413 pounds of cobalt. Canada supplied 73,088 pounds of metal, 288,069 pounds of ore containing 32,710 pounds of cobalt, and 225,609 pounds of oxide estimated to contain 158,100 pounds of cobalt.

Cobalt imported for consumption in the United States, 1940-44, by classes¹

Year	Alloy			Ore			Metal	
	Pounds		Value	Pounds		Value	Pounds	Value
	Gross weight	Cobalt content		Gross weight	Cobalt content

1943	58,928	95,463	—	—	56	164
1944	225,609	400,356	—	—	115	354

¹ In addition to classes shown, 4,796,000 pounds of Burmese speiss, containing 335,721 pounds of cobalt, were reported by processor to Bureau of Mines as imported in 1941; value not available.

² Data not available.

³ Includes 2,384,915 pounds of alloy, containing 980,000 pounds of cobalt and valued at \$867,799, received in December 1942 but recorded as January 1943 by U. S. Department of Commerce.

⁴ Reported by importer to Bureau of Mines; not separately classified by U. S. Department of Commerce.

⁵ Recorded by U. S. Department of Commerce as 12,253,292 pounds, containing 1,995,168 pounds of cobalt and valued at \$2,270,889; these figures, however, include some alloy.

Exports.—Exports of cobalt are relatively small, as is evident from the next table. Cobalt metal and alloys comprised the bulk of the exports in 1943 and 1944, and virtually all went to the Union of Soviet Socialist Republics.

⁴ Pierce, W. G., Cobalt-Bearing Manganese Deposits of Alabama, Georgia, and Tennessee: Geol. Survey Bull. 940-J, 1944, 21 pp.

⁵ Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

CONSUMPTION

Refiners or processors.—Consumption of cobalt contained in alloy, ore, concentrate, and speiss by refiners or processors was 5,457,000 pounds in 1944, compared with 5,394,000 pounds in 1943. In addition, the cobalt content of other cobalt raw materials consumed by refiners or processors in 1944 was as follows: Fines, 283,905 pounds; hydrate, 128,767 pounds; carbonate, 17,838 pounds; low-grade oxide, 1,045 pounds; and rondelles, 788 pounds. Thus, the total cobalt content of cobalt raw materials consumed by refiners or processors was 5,889,343 pounds in 1944, of which 89 percent was processed to metal, oxide, and hydrate, and 11 percent was used in making salts and driers.

Refiners or processors of cobalt in the United States in 1944

Refiner or processor	Location of plant	Cobalt product ¹ made	Cobalt raw material ¹ used

Industrial consumers.—Consumption of cobalt (exclusive of salts and driers) by industrial consumers was 3,988,912 pounds in 1944, an increase of 2 percent over 1943; about 95 percent was used for metallic purposes and 5 percent for nonmetallic applications. The largest use for cobalt in 1944 was for stellite and stellite-type alloys, but 18 percent less cobalt was thus used than in 1943. The second-largest amount was employed in magnets, which used 28 percent more cobalt than in 1943. More cobalt also was used in carbide-type alloys, ground-coat frit, and pigments than in 1943, but less was used in high-speed steel. The quantity of cobalt salts and driers used is not known; however, in 1944 production of salts was 2,044,000 pounds containing 257,000 pounds of cobalt, and output of driers was 6,590,000 pounds containing 396,000 pounds of cobalt.

¹ In addition to countries listed, Brazil, Chile, China, Finland, Germany, Italy, Japan, Mexico, Spain, and Sweden produce cobalt, but production data are not available.

² Produced from Australian ore.

³ Data not available.

⁴ Imports into United States.

⁵ Less than 1 ton.

⁶ Year ended June 30, of year stated.

⁷ Bureau of Mines not at liberty to publish figures.

Belgian Congo.—Belgian Congo continues to be the world's chief source of cobalt. Production data for many years are not available for publication. However, following the German invasion in 1940 of Belgium, where Belgian Congo alloy formerly was processed, the entire output has been shipped to the United States; during 1944 imports were 1,695 metric tons, compared with an average of 1,786 tons during the 4 years 1940-43.

Canada.—Production of cobalt (content) in Canada declined to 38,452 pounds in 1944 from 175,961 pounds in 1943. The decline was probably due largely to the withdrawal of the Metals Reserve Co. as a purchaser of Canadian cobalt. The Silanco Mining & Smelting Corp., N. B. Davis, and the O'Brien custom mill operated by C. V. J.

O'Shaughnessy were the chief producers in 1944. Deloro Smelting & Refining Corp. continued to refine cobalt alloy mainly from Northern Rhodesia and chiefly for the British market. The Silanco Mining & Smelting Corp. has decided to proceed with plans for the erection of a smelter with a capacity for smelting and refining 10 tons of cobalt concentrates daily at Cobalt, Ontario, where the company operates a concentrator and mines cobalt-silver ore from several properties.⁶

Chile.—According to Hudson:⁷

• The production of cobalt has also been increased through the economic cooperation given to the Cobaltera S. A., which is working a deposit of low grade in Freirina. The help of the corporation (Fomento) has made it possible for this company to construct a concentration plant for improving the grade of the ore, and provided the capital necessary to begin production. At the present time the plant is producing approximately 1,000 kilograms of carbonate of cobalt a month. Within a short time it will produce oxide of cobalt which can be readily distributed and sold on the market. At the same time, various cobalt mines are being studied which are near the plant.

Finland.—Finland became a producer of cobalt about 1936, but figures on output are lacking. However, during the three years 1937–39 an average of 202,697 pounds of metal and 105,700 pounds of oxide was imported into the United States from Finland. Finnish cobalt no doubt contributed a large part of Germany's supply before relations between the two countries were broken.

French Morocco.—For a number of years before its occupation by Germany, French Morocco was a relatively small but important producer of cobalt. During the period between the landing of the Allied forces and December 1943 the entire production was allocated to the United States, and 4,529 short tons containing 1,126,641 pounds of cobalt were shipped. In addition to cobalt, the ore contains 5 to 30 grams of gold to the ton. The mine (Bou Azzer) is about 186 miles from the railroad at Marrakech, and because of its inaccessible location and lack of trucks to haul the ore no shipments have been made since December 1943. According to Brooks:⁸

The cobalt mine was opened about 9 years ago * * * and is fairly modernly equipped. Cobalt deposits are not found in a continuous vein or lode but in pockets, making much exploratory work necessary before mining operations can begin. These pockets are in solid rock over a width of about 80 feet. Proved resources are 36,000 metric tons, permitting 10 years' operation at the rate of 300 tons per month, but there is every reason to believe that vastly larger deposits exist. Production is now 200 metric tons per month of 12-percent cobalt. At present the mine has several levels, the deepest being 175 meters (574 feet). * * *

Since the American landing in Morocco and until December 1943, the United States purchased most of the cobalt produced at Bou Azzer. No sales are known to have been made since that month, and there are around 1,400 metric tons of cobalt at the mine and 400 metric tons at the railhead at Marrakech.

Northern Rhodesia.—Northern Rhodesia is second to Belgian Congo as a producer of cobalt. Production data have not been published since 1939, when an output of 1,598 metric tons was recorded.

Spain.—Small quantities of ore averaging about 6 percent cobalt were reported produced in Leon and Oveido Provinces in 1944.

Sweden.—It is reported that cobalt, among other metals, is being obtained from Boliden ore.⁹

SUMMARY

Although domestic output of molybdenum concentrates in 1944 was about 37 percent below the 1943 record, a satisfactory balance was maintained between total production and shipments, and year-end stocks showed an increase of about 8 percent. During the first half of the year production exceeded demand, and producers' inventories rose month by month until they reached a record high of over 18 million pounds (Mo contained in concentrates) at the end of June. Subsequent large export shipments and an increase in domestic consumption absorbed excess stocks.

Imports of molybdenum in 1944 were nearly twice as great as in 1943. However, about one-third of the total comprised concentrates entering the United States from Canada for conversion to molybdenum products and return to the Dominion.

Exports of domestic molybdenum concentrates went to U. S. S. R. and the United Kingdom.

The principal use for molybdenum is in iron and steel products, and consumption follows closely the pattern of alloy-steel production. The 20-percent drop in alloy-steel output in 1944 was reflected in a similar reduction in consumption of molybdenum products.

³ 6 months, July to December.

POSTWAR OUTLOOK

The postwar production of alloy steels—major domestic use of molybdenum products—can hardly be expected to continue at the

wartime level of 10 to 13 million ingot tons a year. As a consequence, the domestic consumption of molybdenum may be expected to drop considerably, although not necessarily to prewar (1938-39) levels. One unknown factor is whether the war-initiated lower alloy steels will continue to be used for engineering purposes or whether there will be a return to the use of steels of previously accepted analyses.

A further potent factor in steel requirements for molybdenum products will be the extent to which the molybdenum-containing high-speed steels are accepted. It seems probable that many of the large users of tool steel will take advantage of the price differential possessed by the molybdenum types and continue to use them for most purposes, as war experience shows them in most instances to be an economic substitute for the conventional tungsten types (18-4-1).

The heat treatment of these steels is, however, more exacting than that of the 18-4-1 types, and this factor may cause the many small individual purchasers to return to the conventional types of high-speed steels.

Considerable foreign demand for molybdenum may be expected both for molybdenum products and for molybdenum-containing alloy steels. Two adverse economic factors would be small foreign buying power and the availability of molybdenum-bearing war scrap.

It seems, therefore, that postwar demands for molybdenum will fall sharply from the 1941-44 levels but should compare favorably with demands in the immediate prewar years.¹

WAR REGULATIONS

No new regulations governing the distribution of molybdenum were issued by the War Production Board in 1944. Molybdenum ingot, wire, and sheets continued on allocation (General Preference Order M-369, December 31, 1943). The only control over molybdenum in other forms was through the requirement that vendors furnish the War Production Board with monthly lists of all sales of molybdenum in excess of 2,000 pounds. Revocation of Direction 1 to Supplementary Order M-21-h and Supplementary Order M-21-g in January 1944 removed all restrictions from formulas for the production of molybdenum-containing and certain other alloy steels.

PRICES

Since 1938 molybdenum concentrates have been quoted in trade journals at 45 cents per pound of MoS_2 in 90-percent concentrates. This quotation represents an open market price, but contract deliveries are doubtless at a somewhat lower figure. There is no Government control over the price of concentrates.

The following quotations for molybdenum products conform to the prices established by the Office of Price Administration in MPR 489, dated November 8, 1943.

Product:	Per pound contained Mo
Ferromolybdenum.....	\$0. 95
Molybdenum oxide, technical (powder or briquets).....	. 80
Calcium molybdate.....	. 80

¹ See Minerals Yearbook, 1943, p. 651.

UNITED STATES

PRODUCTION IN 1944

Throughout most of the year domestic production of molybdenum concentrates exceeded shipments, and producers' inventories rose at midyear to over 18 million pounds of Mo contained. Increased demand in the latter half of the year reduced producers' stocks as of December 31 to approximately the quantity of concentrates on hand at the beginning of 1944. Shipments for export, reported by producers, were about 13 percent of total shipments.

Domestic shipments from 1914 to 1944, inclusive, are shown in the accompanying table:

Molybdenum in ore and concentrates shipped from mines in the United States, 1914-44¹

Year	Pounds	Value ²	Year	Pounds	Value ²

¹ For shipments by years, 1914-38, see chapter of this series for 1941.

² Largely estimated by Bureau of Mines.

³ No shipments in 1920 and 1921.

⁴ Revised figure.

Recovery of molybdenum by copper producers continued at about the same rate as in 1943, but owing to smaller output by other producers copper ores contributed about 35 percent of the total domestic production compared with about 22 percent in 1943. As the accompanying table indicates, only 3 of the 11 domestic producers of molybdenum concentrates in 1944 obtained their product from molybdenum ore; the others recovered molybdenum as a byproduct of copper or other operations. The molybdenum content of ores treated ranges from as little as 0.02 percent in some copper ores to 5.75 percent in the Questa (N. Mex.) molybdenite ore. The Climax ore averages only about 0.6 percent, and the success of the enterprise is due to the enormous quantity of ore available as well as to the efficient mining and milling program that has been developed throughout the years.

REVIEW BY STATES

Arizona.—In 1944 four producers recovered a total of 4,270 tons of molybdenum concentrates containing 834,000 pounds of Mo. All were byproduct operations—three from copper mining and the fourth from complex (gold-silver-lead, zinc-molybdenum-vanadium) ores.

Miami Copper Co. began producing molybdenite in 1938 from copper ores mined at Miami, Ariz. The concentrates are roasted at the company plant and shipped to an eastern market. Bagdad Copper Corp., which had been experimenting with molybdenum recovery for some time, began shipments early in 1944 and apparently has succeeded in lowering the copper content of molybdenum concentrates to an acceptable figure. Year-end shipments by the Squaw Peak Copper Mining Co., Camp Verde, Ariz., to Metals Reserve Company, Phoenix, Ariz., constitute the only purchases of domestic molybdenum under the small-lot purchasing program announced July 8, 1943.²

During the first half of 1944 Mammoth-St. Anthony, Ltd., recovered molybdenum from complex ores mined at Tiger, Ariz., and produced calcium molybdate. Molybdenum operations were suspended in July in order that the company might concentrate its efforts on lead and zinc production. Shortly thereafter the Mammoth shaft and some buildings were damaged by fire.

California.—The United States Vanadium Corp. continued recovery of molybdenite concentrates from tungsten operations at Bishop, Calif. The ore also contains a powellite mineral from which molybdenum trisulfide is extracted. Shortage of manpower caused productive mining operations to be suspended late in the year.

Colorado.—Although producing at approximately half the phenomenal rate of 1943, Climax Molybdenum Co. continued as the leading producer of molybdenum in the world. Production was 22,527 short tons of molybdenite concentrates, containing 23,608,421 pounds of molybdenum, compared with 45,589 tons, containing 46,133,715 pounds, in 1943. Many articles have been published describing mining and milling methods employed by the company. Among those that appeared in 1944 are the following:

BUCKY, PHILIP B. Block Caving at Climax. *Explosives Eng.*, vol. 22, No. 2, March–April 1944, pp. 76–79.

CUTHBERTSON, R. E. Unusual Reagent Combination Improves Flotation at Climax Molybdenite Mine. *Am. Inst. Min. and Met. Eng., Tech. Pub.* 1675, 19 pp.; *Min. Technol.*, vol. 8, January 1944.

WHEELER, E. S. Climax Conversion Practice. *Am. Inst. Min. and Met. Eng., Tech. Pub.* 1718, 11 pp.; *Metals Technol.*, vol. 11, August 1944.

The paper by Wheeler is of special interest in that it describes in considerable detail the company processing plant at Langeloth, Pa., and the methods employed for producing calcium molybdate, roasted concentrates and briquets, ferromolybdenum, pure oxide, sodium molybdate, and molybdenum silicide. Shipments of molybdenum products from 1924 to 1942 are also given.

Production of molybdenum concentrates at the Urad property near Empire, Colo., was begun in May 1944 by the Molybdenum Corp. of America and continued throughout the year. Labor shortages hampered both underground and surface operations and prevented capacity operation of the 200-ton mill. The crushing plant is large

² For description of plant see: *Mining World*, Squaw Peak-Initial Pilot Plant Runs Indicate Promising Future for Molybdenum Development, Camp Verde, Ariz.: Vol. 6, No. 9, September 1944, p. 36.

enough to permit expansion of the flotation unit. It is understood that problems encountered in working out the flow sheet have been solved. A description of the mine and mill appeared in Skillings' Mining Review.³

Nevada.—Molybdenum has been recovered since 1941 at the McGill copper concentrator of Kennecott Copper Corp. In addition to copper ore from Kennecott's Ruth mine and its Copper Flat open pit, ore produced at the Consolidated Coppermines Corp. Emma Nevada group is milled; the ores are mixed before treatment. Production figures for the McGill concentrator were not reported separately to the Bureau of Mines until 1944.

New Mexico.—The two producers of molybdenum in New Mexico continued production throughout the year. The Molybdenum Corp. of America mine near Questa has been operated since 1919 and is one of the three properties in the United States worked solely for molybdenum. Mining operations have been simplified somewhat by the driving of a new tunnel. The Chino Mines Division of Kennecott Copper Corp. has recovered molybdenum as a byproduct of copper operations since 1937.

Utah.—Byproduct recovery of molybdenum from copper ore milled by the Utah Copper Co. at Arthur and Magna is the second largest domestic source of molybdenum. The company is the only producer in the State.

EXPLORATION AND DEVELOPMENT

A report of investigation,⁴ published recently by the Bureau of Mines, summarizes exploration by the Bureau during the past 2 or 3 years at the following properties: Amargosa Molybdenum Corp., Pima County, Ariz.; Big Ben mine, Cascade County, Mont.; Boy Scout and Moss properties, Halifax County, N. C.; and Muir Inlet, southeastern Alaska.

The Geological Survey made no new examinations of molybdenum deposits in 1944. Further geologic work was carried on, however, at the Hall property, Nye County, Nev., and the Starr property, Okanogan County, Wash. Geologic investigations of several known deposits are contemplated for the coming year to complete a survey of the larger molybdenum deposits of the United States.

Preparations have been made to release the maps of the Starr and Big Ben deposit, Cascade County, Mont., during 1945.

The Geological Survey made no extensive investigations of molybdenum deposits in Alaska during 1944. In the course of other work, a small deposit of apparently low-grade molybdenum was briefly examined near the southern end of the Kaiyuh Hills, about 70 miles south of the town of Kaltag. The gold-copper-molybdenum deposit at Orange Hill, Chisana district, was also briefly examined.

CONSUMPTION AND USES

Molybdenum is consumed principally in alloy-steel ingots and castings. It is used also in iron castings, and a small quantity is

³Skillings' Mining Review, Urad Molybdenum Mine in Colorado: Vol. 33, No. 47, Mar. 10, 1945, p. 1.

⁴Jullien, C. E., and Moon, Lowell B., Summary of Bureau of Mines Exploration Projects on Deposits of Raw Material Resources for Steel Production: Bureau of Mines Rept. of Investigations 3801, 1945, pp. 32 and 33.

employed in pigments and colors, welding-rod coatings, and miscellaneous chemical products. Because molybdenum is readily available from domestic sources and can be used in place of other less-abundant steel-alloying elements, it has been an important material in the war program. Molybdenum concentrates usually are converted to molybdenum products, such as ferromolybdenum, calcium molybdate, and molybdic oxide (roasted molybdenite) before being used. In recent years the oxide, in cans or mixed with a pitch binder to form briquets, has found great favor with consumers. These cans and briquets, each of which contains an exact quantity of Mo, make possible the addition of this relatively expensive alloying material without the necessity of maintaining a weighing room. Moreover, molybdenum in the oxide form can be thus introduced into steel at a substantially lower cost. Shipments for export are predominantly in the form of concentrates and ferromolybdenum; the latter material has the advantage of requiring a smaller volume of shipping space for a given weight of contained Mo. A small quantity of concentrates (about 60,000 pounds of contained Mo in 1944) is used by a few steel companies as an addition to the molten metal in the ladle to raise the sulfur content to improve machinability, in addition to gaining the benefit of the contained Mo.

The Bureau of Mines has collected molybdenum-consumption figures since July 1941. A complete coverage of consumers of molybdenum products was maintained until January 1944, when a number of small users, taking about 5 percent of the December 1943 consumption, were relieved from further reporting. Although the 1944 totals given in the accompanying table are not directly comparable with those for the two preceding years, the indicated relative demand for individual products is believed to be reliable.

Consumption of molybdenum products in the United States, July 1941–December 1944, in thousands of pounds of contained molybdenum

Year	Ferromolybdenum	Calcium molybdate	Molybdenum oxide ¹	Other ²	Purchased scrap	Total
1941 ³	3,899	2,724	6,546	372	510	14,051
1942	10,673	5,501	27,824	414	1,252	45,664
1943	6,663	5,099	26,383	580	2,940	41,665
1944	4,617	2,351	21,303	631	2,777	31,679

¹ Includes also molybdenum trioxide and molybdic acid, 1942–44.

² Ammonium molybdate, sodium molybdate, molybdenum silicide, molybdenum metal, and alloys; also molybdenum trioxide and molybdic acid in 1941.

³ July to December.

The volume of molybdenum consumed in the form of metal is insignificant. However, this item is of considerable importance; and, as noted in the discussion of War Regulations, molybdenum metal is the only molybdenum product under allocation. Production of wire, rod, and sheet for lamps and tubes requires technical skill by trained workers and is performed by only a few companies in the United States. The process employed by one producer has been described in steel.⁴

The percentages of Mo used in steel cover a considerable range. The molybdenum high-speed tool steels may contain as much as 9

⁴ Steel, Drawing Tungsten and Molybdenum Wire: Vol. 116, No. 13, Mar. 26, 1945, pp. 90–91, 110.

percent Mo whereas the Mo content of engineering steels does not often exceed 0.30 percent. The ratio of production of molybdenum-containing high-speed steels to straight tungsten high-speed steels varies with the relative abundance of the two elements. For example, during 1942 and part of 1943, 75 percent of all high-speed steel orders accepted in any one quarter were required to be of the molybdenum type and not more than 25 percent of the tungsten type. Molybdenum high-speed steels have been investigated by various steel companies for many years. Probably the best-known early patents are those of the Cleveland Twist Drill Co., covering the now widely distributed Mo-Max type. The basic composition is approximately as follows: Carbon 0.78–0.84 percent, chromium 3.50–4.00, molybdenum 8.20–9.40, tungsten 1.30–2.00, and vanadium 1.00–1.30. In the fall of 1944 three motor companies were reported⁶ to be advocating standardization of a 6 Mo–6 W type of high-speed steel developed by the Allegheny Steel Corp. A typical analysis of this steel is: C 0.79–0.87 percent, Cr 3.90–4.40, W 6.00–6.75, Mo 4.75–5.25, and V 1.75–2.05. (In this analysis the lower molybdenum content is offset by an increase in vanadium.)

During the war years every effort has been made to substitute the lower-alloy-content NE (National Emergency) steels for the conventional SAE steels, to conserve critical alloying elements used as additives. Currently used NE steels containing molybdenum are in the following series: NE 52100–A–B–C, NE 8600, 8700, 9400, 9700, 9800, and 9900. Analyses of NE steels and lists of their uses were published in *Metal Progress*;⁷ the part played by molybdenum in the NE steel program is discussed in a comprehensive review by Mather.⁸

The feasibility of using battlefield scrap with a high nickel, chromium, and molybdenum content is discussed in a current article in *Steel*.⁹

FOREIGN TRADE¹⁰

Imports have never been an important factor in the molybdenum industry of the United States. In most years they have amounted to only a few thousand pounds of molybdenum in ores and concentrates. The advent of receipts from Chile in 1942 had a noticeable effect upon import totals, which have about doubled each year subsequently. However, none of the material recorded in the accompanying import table enters domestic trade. (Additional molybdenum from Mexico, which entered the United States in bond for export, is not included in the record of "imports for consumption.") Molybdenum concentrates received from Canada are converted to molybdenum products at a processing plant in the eastern United States and returned to Canada.

Export statistics of molybdenum ores and concentrates have been compiled by the United States Department of Commerce since 1939. No official records are available for earlier years, but various estimates

¹⁰ Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

of export shipments published from time to time were usually in the range of 50 to 75 percent of the United States total shipments. During the war years exports of molybdenum in concentrates have represented about 25 percent or less of total shipments from domestic mines. In 1944, exports were only 15 percent (13 percent if material of Canadian origin is excluded) compared with 19 percent in 1943 and 17 percent in 1942. In addition, considerable quantities of ferromolybdenum are shipped abroad. In 1944, 4,427,581 pounds of ferromolybdenum valued at \$2,665,920 were exported compared with 1,115,844 pounds valued at \$710,224 in 1943 and 6,089,953 pounds valued at \$3,317,301 in 1942.

Imports and exports of molybdenum ore and concentrates in 1943 and 1944 appear in the accompanying tables.

WORLD PRODUCTION AND DEVELOPMENTS

Although authoritative information on production of molybdenum outside the Western Hemisphere is meager, it is reasonable to assume that the United States continued to lead all countries in producing this vital war material. Output of molybdenum concentrates and molybdenum products in the United States was sufficient not only to

meet the needs of domestic steel companies but to supply requirements of our Allies—notably U. S. S. R. Clues to supplies of molybdenum and other steel-alloying elements available to Germany and Japan have been found through studies of enemy ordnance recently made public.¹¹ Examinations of matériel indicated that, next to copper and nickel, Germany was probably most cramped for molybdenum. However, molybdenum appears to have been used freely in armor and projectiles. The high molybdenum content of Japanese light armor suggests that the Japanese had ample stock piles of alloying elements to enable them to use the more conventional alloy steels.

World production of molybdenum in ores and concentrates, 1938-44, by countries, in metric tons

¹ Gross weight of ore and concentrates reported; molybdenum content estimated by authors.

² Estimate included in total.

³ Less than 1 ton.

⁴ Estimate.

⁵ Revised figure.

⁶ Estimate for Greece, Rumania, and Yugoslavia included in total; in addition, molybdenum ore is reduced in Burma, China, Chosen, Finland, France, Japan, Manchuria, Sweden, and U. S. S. R., but data of production are not available.

Canada.—The Government-stimulated molybdenum development program undertaken in 1941 resulted in a substantial increase in production of molybdenite concentrates in the Dominion. The price incentive of 85 cents per pound of contained sulfide in concentrate containing 80 percent or more (compare U. S. market quotation of 45 cents per pound for 90-percent concentrate) was an influential factor. By the end of 1943 a favorable supply situation had been reached, due largely to production by three producers—Indian Molybdenum, Ltd., Abitibi region, Quebec; the La Corne mine near Val d'Or, Quebec; and the Quyon Molybdenum Co., at Quyon, Quebec. By April 1944 there was reported to be between 2 and 3 years' supply of molybdenum concentrates on hand, and the Canadian Government canceled its contract with Indian Molybdenum, Ltd. Production ceased at that property on April 30, 1944. Molybdenum ore milled (68,750 tons) at the Indian Molybdenum property during the first 4 months of 1944 yielded 567,535 pounds of molybdenite.¹² Nearly all the remainder of 1944 production of molybdenum came from the La Corne project, operated by Wartime Metals Corporation. The total was about 163 percent greater than in 1943. According to

¹¹ Cady, J. R., Gillett, H. W., and Grenell, L. H. (Battelle Memorial Institute), *Enemy Matériel from the Metallurgical Point of View: Metal Progress*, vol. 47, No. 2, February 1945, pp. 280-320.

¹² Dome Mines, Ltd., *Annual Report for Year ended December 31, 1944*.

G. Shartner,¹³ manager of the La Corne molybdenum project, the 300-ton mill recovers 60 tons of 85-percent concentrate per month from the treatment of about 7,000 tons of ore; 125 tons of concentrate had accumulated at the mine up to the end of November 1944. Throughout the year Canadian concentrates were shipped to a processing plant in the United States for conversion to molybdenum products and returned to the Dominion. A review of wartime production of molybdenum in Canada and a table of production from 1902 to 1943, inclusive, appear in the 1943 Report on Miscellaneous Metals in Canada.¹⁴

Chile.—Molybdenite concentrates have been recovered from copper operations of the Braden Copper Co. since 1939. The Chuquicamata mine of the Chile Exploration Co. and the Potrerillos mine of the Andes Copper Co. have been investigated as sources of molybdenum, but recovery has not been undertaken.

Egypt.—Prospecting for molybdenite took place during 1944 near Gebel Qatter, west of the oil wells at Hurghada in the Red Sea area. Other occurrences in this area have been described by Hume.¹⁵

Germany.—Statements emanating from officials of the British and United States Governments have been widely reprinted and agree that the loss of Finland, Greece, Rumania, and Yugoslavia has deprived Germany of two-thirds of its molybdenum supplies. The production at Knaben, Norway, which was seriously curtailed by Allied bombing in 1943, is believed to be inadequate for steel needed for replacements of war matériel.

Mexico.—The decline in production of molybdenum in Mexico from 1,118 metric tons in 1943 to 717 metric tons in 1944 was due largely to labor difficulties at the Greene Cananea mine, which is the leading source of molybdenum in that country. Except for small purchases by Metals Reserve Company, all shipments are transshipped through the United States under bond and are not included in either the import or export statistics of the United States. During the war period Mexican molybdenum has been purchased by the United States for shipment to the Allied Nations.

Peru.—According to Vanderburg,¹⁶ the Peru Molibdeno, S. A., only steady producer of molybdenum in Peru, closed its concentrator in October 1944 because of lack of ore but continued exploration and development work. In 1944 the company milled 23,104 metric tons of ore averaging 0.453 percent MoS_2 , from which 104.1 metric tons of concentrates containing 82.73 percent MoS_2 were recovered. The Metals Reserve Company contract with Peru Molibdeno for the purchase of molybdenum concentrates, dated May 1, 1943, was canceled on January 12, 1945, effective 90 days from the date of notification.

Rumania.—Production of molybdenum is reported to have increased considerably during the war years. Interest in developments in the Rumanian industry lies not so much in the volume of production, which is not impressive when compared with that of Western Hemisphere countries, but in its relationship to Germany's supply of ferro-alloying metals. Apparently the accelerated rate of production in Rumania served as partial compensation for losses in other fields.

The principal producer has been Molybden, S. A., of Bucharest, which obtains molybdenum from molybdenum-bismuth ore mined at Baita, Judetul of Bihor.

*Sweden.*¹⁷—Wartime search for molybdenum continued in several areas in Sweden during 1944. Before the war Sweden is not known to have produced molybdenum, and the requirements of the Swedish steel industry were met from outside sources. An annual output of 90,000 tons of ore "with a considerable molybdenum content" is anticipated from the Ål mine in Lillhärad Parish. The Swedish Geological Survey reported the discovery of low-grade molybdenum deposits in 1943 at Aijajarvi in the Parish of Jukkasjärvi in northern Sweden. Small quantities of molybdenum were also discovered at the Drugge mine in the Parish of Jokkmokk. During 1943 the Riddarhytte A. B. began recovering molybdenum at the Källefallat mine at Riddarhyttan in Västmanland Province and built a concentration plant. Treatment of waste material from the operation, containing between 0.1 and 0.2 percent MoS_2 , began in 1944. Deposits of associated molybdenum and tungsten ores are reported as being worked in the Yxsjö and Hork fields, Örebro County.

U. S. S. R.—Although production statistics are lacking, references in the press to exploitation of numerous molybdenum deposits in Russia indicate that molybdenum has been produced since 1918.¹⁸ As in the United States, molybdenum has been recovered from molybdenum ores and also as a byproduct of copper operations. In 1944 discovery of a deposit of molybdenum ore ranging from 0.6 to 0.8 percent Mo was reported in Azerbaidzhan. The property apparently offered sufficient promise to justify construction of a mill, power plant, and housing facilities for workers.¹⁹ Molybdenum recovery continued at the copper operation on Lake Balkhash in Kazakstan,²⁰ where a molybdenum plant was built in 1940.

SUMMARY

Domestic production of vanadium ores in 1944 dropped to 3,527,054 pounds of contained vanadium from an all-time high of 5,586,492 pounds recorded in 1943. Metals Reserve Company purchases of vanadium ore, which comprised about 43 percent of the total 1943 mine shipments, in terms of contained metal, ceased at the end of February 1944 and represented only about 10 percent of the 1944 shipments. Lacking the stimulus afforded by the Government purchasing program, many small producers withdrew from vanadium mining. Although reserves of vanadium-bearing materials are scattered widely over the United States, commercial production comes from five Western States of which Colorado is the leading one.

Imports of vanadium, largely in the form of concentrates, were all from Peru. The 1944 total was the smallest since 1937. Exports of ore and concentrates were insignificant, but an appreciable quantity of ferrovanadium was shipped abroad.

Consumption of domestic vanadium ores, although 20 percent below the 1943 total, was maintained at a high figure, largely because of the installation of certain facilities for reworking waste vanadium-containing materials.

Salient Statistics of the vanadium industry in the United States, 1941-44, in pounds of vanadium contained

POSTWAR OUTLOOK

The commercial position of vanadium in the postwar period is markedly similar to that of molybdenum,¹ with the single exception that vanadium is not substitutable for tungsten as is molybdenum. It is to be expected, therefore, that vanadium consumption will drop from wartime levels to a point near the 1935-39 average.

¹ Jenckes, Edwin K., and van Siclen, Alice P., Molybdenum; Bureau of Mines Minerals Yearbook 1944, section on Postwar Outlook.

The restrictions on uses of vanadium were much more severe than those placed on other alloying additives used in the production of alloy steels, and there would seem, therefore, to be a very large backlog of unsatisfied civilian demand for vanadium-containing steels. Enforced wartime economics have resulted in reappraisal of the utility of vanadium in some applications, but, unquestionably, wartime experience also has developed new requirements for the element.

No attempt can be made to estimate closely the probable postwar domestic production of vanadium ore because of possible shifts between domestic and foreign sources of supply. Present stocks of vanadium ores and partly or fully refined vanadium-bearing materials seem to be adequate to take care of any predictable emergency.

WAR REGULATIONS

Allocation controls over the distribution of vanadium, provided by War Production Board General Preference Order M-23, were removed on December 30, 1943, by amendment of the order. However, under the amended order, sellers are required to report to the Board all sales of 500 pounds or more of vanadium in ferrovanadium or commercial vanadium pentoxide in any one month. Order M-21-a provides for submission of melt schedules to the Board for authorization of the use of vanadium in alloy steels. Effective October 1, 1944, imports of vanadium ceased to be subject to Government control under General Imports Order M-63.

PRICES

Vanadium ore has been quoted in trade journals at 27½ cents per pound of contained V_2O_5 since 1935. As a result of wartime demand for vanadium, prices actually paid have been at a considerably higher level, and in 1944 sales to Metals Reserve Company at as much as 60 cents per pound were reported. Private mill operators apparently purchased ores at lower figures. No standard price schedule was issued by the Metals Reserve Company, and all purchases by that agency were made on the basis of individual contracts, depending on grade of ore, distance from purchase depots, and other factors. The price of vanadium ore is not governed by Office of Price Administration Maximum Price Regulation 489, which became effective November 8, 1943. The Regulation does, however, provide for the following prices for ferrovanadium and vanadium pentoxide, which remained in effect throughout 1944:

Ferrovanadium.—Per pound of contained vanadium, standard crushed sizes, f. o. b. Niagara Falls, N. Y., or Bridgeville, Pa., freight allowed to destination for 25 pounds or over:

A—Open Hearth, minimum 30 percent V. (Trade journal quotations specify a minimum 35-percent vanadium content).....	\$2. 70
B—Crucible, minimum 35 percent V.....	2. 80
C—Primos, minimum 35 percent V.....	2. 90
Spot prices, 10 cents per pound higher.	

Vanadium pentoxide.—Per pound of contained V_2O_5 , air-dried or fused vanadium pentoxide, f. o. b. Niagara Falls, N. Y., or Bridgeville, Pa., with freight allowed to destination on 25 pounds or over:

(1) Maximum base contract price, any quantity.....	\$1. 10
(2) Maximum base spot price:	
500 pounds and over.....	1. 15
Less than 500 pounds to 10 pounds.....	1. 20
Under 10 pounds.....	1. 25

Vanadium is also marketed in the form of special alloys, such as the Grainal series. Grainal No. 1, containing 25 percent vanadium, is quoted at 87.5 cents per pound of alloy, and Grainal No. 6, containing 13 percent vanadium, at 60 cents per pound.

MINE PRODUCTION AND TREATMENT OF ORES

The termination of the Metals Reserve Company domestic vanadium ore-purchasing program on February 29, 1944, was the outstanding event in the industry in the United States during the year. Removal of the price incentive and ready market for marginal ores caused many small independent operators to cease mining vanadium ores. In contrast to the 216 operators who reported production in 1943, only 82 are known to have shipped in 1944, and more than half of these shipped to the Metals Reserve Company only during the first 2 months of the year. Many of the producers of 1942 and 1943 who had mined as individuals or as members of family groups entered the armed forces, and production from their claims ceased.

The responsibility for maintaining a domestic vanadium-mining industry therefore reverted to the two major producers—United States Vanadium Corp. and Vanadium Corp. of America. Their operations, through mining, leasing, and purchasing from small operators, extended over the Southwest Colorado-Southwest Utah and Northeast Arizona-Northwest New Mexico area. Some of the miners who had formerly sold to Metals Reserve Company marketed their vanadium ores to the large mill operators, but others found it impracticable to meet the higher ore specifications and lower prices offered by industry.

The United States Vanadium Corp. and Vanadium Corp. of America, which had acted as agents for Metals Reserve Company during the domestic purchase program, gradually severed their connections, as purchasers and refiners, and by the end of 1944 mining and milling operations were largely for private account.

The United States Vanadium Corp. acted as agent for Metals Reserve Company in purchasing domestic vanadium ores from July 1942 until the end of February 1944. The Government-owned ores were milled by United States Vanadium Corp. at the Defense Plant Corporation plant at Durango, Colo., and at the Nisley & Wilson mill at Gateway, Colo., and by Vanadium Corp. of America at Monticello, Utah. Operation of these mills on behalf of the Government was suspended in the spring of 1944, but in October the United States Vanadium Corp. purchased the Durango mill and began treating the Metals Reserve Company stock pile at Durango on a toll basis. Early in 1945 the Vanadium Corp. of America purchased the Monticello stock pile and leased the Defense Plant Corporation plant there. The Gateway stock pile was sold to United States Vanadium Corp. and moved to the mill location at Uravan. By the end of March 1945 all domestic vanadium ores purchased by Metals Reserve Company had been disposed of except the untreated remainder of the Durango stock pile and a small stock of Nevada lead vanadate ore and concentrates.

REVIEW BY STATES

Arizona-New Mexico.—Vanadium mining in this southern portion of the four-States area in 1944 consisted largely of lessee operations of Vanadium Corp. of America and mining by Wade, Curran & Co. on the Apache Reservation in the Carrizo Mountains.

The recovery of vanadium from complex ores at Tiger, Ariz., and the production of sodium vanadate by Mammoth-St. Anthony, Ltd., were suspended in the summer of 1944. The recovery process employed by the company was described in *Mining World*.² Announced program of the company to discontinue temporarily the production of vanadium, molybdenum, and gold, in order to use entire mill facilities for the production of lead and zinc, was thwarted in September when fire destroyed the Mohawk shaft and part of the surface plant. By concentrated effort 700 feet of the shaft was retimbered in 40 working days.⁴

Colorado.—In 1944, Colorado was again the leading producer of vanadium ores. The largest single vanadium property, at Rifle Creek, was worked by the United States Vanadium Corp. The area was examined and mapped by the Geological Survey in the summer of 1944, and a preliminary report and map were issued in December of that year. The following paragraphs are quoted from the report:⁵

Vanadium ore is being mined from two deposits in the Entrada sandstone, at the Rifle and Garfield mines, about 13 miles northeast of Rifle, Garfield County, Colo. The deposit at the Rifle mine has been the most productive of the vanadium-bearing sandstone type of deposit. It was mined from 1925 to 1932, and the current period of mining began in 1941. The Garfield mine was operated at intervals before 1942 and has been in continuous operation since that time. Small deposits of vanadium ore have also been mined from the Morrison formation in the area shown on the map and in the adjoining area to the east. The total production of vanadium ore from all of these deposits is about 500,000 tons. * * *

Conclusions.—The present knowledge of the deposits in the Entrada sandstone suggests that the close association of the deposits with the thicker part of the altered zone at the top of the "Red Beds," and the special relationship of the ore bodies in one unit of the Entrada to those in the other, appear to be the only positive guides in searching for new ore bodies. The deposits in the Morrison are confined to the lower part of the formation, but the location of undiscovered ore bodies within these beds cannot be predicted. The genesis of the deposits and the controls that localized the ore are not definitely determined, and all of the evidence concerning them cannot be presented in a brief statement.

The greater part of the domestic vanadium ore milled for private account was treated at the United States Vanadium Corp. mill at Rifle. The present 200-ton mill was reconstructed from one used

during the earlier period of operation (1925-32); production was resumed in February 1942.⁶⁷

The smaller (100-ton) mill at Durango was built in 1942 largely from materials remaining from a plant originally constructed in 1881.⁸ The mill was operated for Metals Reserve Company by United States Vanadium Corp. from August 1942 until early 1944, when all but the acid leaching plant for treatment of tailings was closed. The mill was purchased by United States Vanadium Corp., and treatment of vanadium ores (virtually all from the Durango stock pile) was resumed on a contract basis in October 1944.

The 75-ton mill of Vanadium Corp. at Naturita operated continuously throughout the year.

At Uravan, Colo., the 300-ton mill used by United States Vanadium Corp. for its own milling operations was inactive during most of the year. Improved recoveries are said to have been obtained from a new filter design at the mill.⁹

The North Continent Mines, Inc., which had operated at Slick Rock, San Miguel County, for about 10 years, closed its 20-ton mill at the end of 1944, and subsequent announcement was made of approval by the Securities and Exchange Commission of the sale of the mine, mill, and equipment to the Union Mines Development Corp.¹⁰

*New York.*¹¹—The possible recovery of vanadium from titaniferous magnetites of the Adirondacks continues to be of interest but has not yet been undertaken commercially. Preliminary work has been performed by the National Lead Co. in reopening old workings on Sanford Hill, and Bethlehem Steel Co. has investigated the recovery of vanadium from slag from pig iron reduced from the magnetite sinter.

The accompanying table shows total production by the major and smaller producers, by States. Owing to the difficulty of obtaining reports from all vanadium miners, many of whom are transients, mine production is reported here in terms of receipts at processing plants and purchasing depots.

Although the greater part of the vanadium oxide produced in the United States comes from domestic vanadium ores, additional quantities are recovered from phosphate rock mined in Idaho, from imported ores and concentrates treated at Bridgeville, Pa., and as a byproduct at Glens Falls, N. Y.

EXPLORATION AND DEVELOPMENT

Four exploration projects on showings of vanadium have been described in a recent report of the Bureau of Mines.¹²

Reserves totaling more than 20 million tons averaging about 1 percent V_2O_5 were shown at the following localities:

Ashland Vanadium, Clay, Coosa, and Chilton Counties, Ala.

Started: July 1943.

Exploration: 2,500 ft. of diamond drilling and trenching.

Reserves: 5,076,000 tons ± 0.10 percent V_2O_5 .

Remarks: Working on recovery of the vanadium from the schist. No further development planned.

Southwest Colorado and Southeast Utah.

Started: May 1943. Finished: December 1943.

Exploration: 38,598 ft. of diamond drilling and sampling.

Reserves: 40,000 tons 1.25 percent V_2O_5 .

Remarks: Auxiliary reserve of vanadium ore.

Mercur Dome, Tooele County, Utah.

Started: September 1943. Finished: November 1943.

Exploration: 300 ft. diamond drilling, 68 ft. hand auger, and workings sampled.

Reserves: 4,600 tons 0.717 percent V_2O_5 .

Remarks: The vanadiferous shale bed probably covers an area of several square miles, and the thickness is about 5 ft. Metallurgical tests indicate that extraction of V_2O_5 will be difficult.

Southwest Wyoming—Lincoln County, Wyo.

Started: July 1943. Finished: December 1943.

Exploration: 90 trenches dug along 20 miles of outcrops; 7 adits driven for a distance of 544 ft.; 4 shafts sunk along fault for a total of 110 ft.

Reserves: 18 million to 25 million tons, 0.90 to 1.0 percent V_2O_5 .

Remarks: The vanadium occurs in thin shale beds within the Phosphoria formation. The vanadium-bearing shales are about 3 ft. thick and appear to be continuous over the area.

The Bureau's work on treating vanadium-bearing materials from various domestic sources has been described in an article by Johnson and Davis,¹³ from which the following excerpts are taken:

Dry differential grinding of carnotites from Colorado and Arizona (containing 2.3 to 4.7 percent V_2O_5) followed by air separation effected recoveries from 70 to 78 percent at a concentration ratio of 3 to 1 and in one case 86.3 percent at a $2\frac{1}{2}$: 1 ratio.

Flotation tests on a Nevada ore containing 1.7 percent V_2O_5 , chiefly as cuprodescoizite, showed that concentrates with 8.82 percent V_2O_5 can be made with 88 percent recovery of the vanadium.

A vanadinite ore from Arizona assaying 0.35 percent V_2O_5 proved susceptible to flotation. A concentrate containing 15.4 percent V_2O_5 and 59.7 percent Pb was produced by standard procedure, with recoveries of 75 and 92.3 percent, respectively * * *.

The * * * refractory nature [of the low-grade ore of the Idaho-Wyoming vanadium area] poses a difficult metallurgical problem, which is being investigated in the Bureau laboratories at Salt Lake City. It has been found that about 85 percent of the vanadium and phosphorus can be extracted by roasting the ore with salt (NaCl) and pyrite. The roasted residue is water-leached, which dissolves most of the vanadium; then leached with sulfuric acid, which removes

¹² Jullihn, C. E., and Moon, Lowell B., Summary of Bureau of Mines Exploration Projects on Deposits of Raw Material Resources for Steel Production: Bureau of Mines Rept. of Investigations 3801, 1945, pp. 32-33, 35.

¹³ Johnson, A. C. and Davis, C. W., War Development Proves Large Vanadium Reserves: Eng. and Min. Jour., vol. 146, No. 4, April 1945, pp. 105-107.

most of the phosphorus. Two products, one high in vanadium and the other suitable for use as a phosphate fertilizer, have been thus recovered. * * *

The Bureau has recently discovered vanadium associated with greenish mica that forms an important constituent of the graphite ores occurring near Ashland, Ala., which may be an important source. The little metallurgical research done indicates that a concentrate containing 0.5 percent V_2O_5 can be obtained as a byproduct of the local graphite operations. Possibly the concentrate grade can be increased. * * *

* * * The most feasible method [of recovering vanadium from titaniferous magnetites occurring in New York] appears to be to recover the vanadium in pig iron, which could be blown in a converter to produce a slag with enough vanadium for the production of ferrovanadium in another furnace operation. Tests in an experimental blast furnace at the Bureau's Minneapolis station indicate that 87 percent of the vanadium can be recovered from the pig iron. Fairly satisfactory operating conditions were maintained as long as the titania content of the slag did not exceed 10 percent. * * *

The Geological Survey continued investigations of vanadium deposits in the sandstones of the Colorado Plateau region of Colorado, Utah, Arizona, and New Mexico and released an excellent geologic map of the vanadium region of Southwest Colorado and Southeast Utah. Additional geologic work was done in the Thompsons (Utah) and Gateway (Colo.) districts; maps of these areas will be issued in 1945. The Rifle (Colo.) area was mapped, and a map and short text were released. A report on vanadium in the phosphatic shales of Idaho and Wyoming is in preparation.

FOREIGN TRADE ¹⁴

Vanadium is imported into the United States as ore, concentrates, and flue dust. In 1944, all imports of vanadium ore or concentrates were from Peru. As most of the imports were in the form of concentrates, the average vanadium content of the material was appreciably higher than in the previous year. Vanadium-bearing flue dust comprises a small part of the import total. However, additional quantities of vanadium are recovered in the United States from flue dust and boiler scale from ships burning Venezuelan oils.

Exports of vanadium ore and concentrates are very small. Most shipments to foreign countries are in the form of ferrovanadium; a small quantity of vanadium oxide (33,084 pounds in 1944) is also exported. Exports of ferrovanadium were 1,191,996 pounds, valued at \$2,212,490, in 1944 compared with 444,457 pounds, valued at \$518,322, in 1943. Most of the ferrovanadium shipped in 1944 went to the U. S. S. R.

WORLD PRODUCTION AND DEVELOPMENTS

Complete information on vanadium production in 1944 is not available, but preliminary figures indicate a world output near that of 1941. Production by the three principal producing countries—the United States, Peru, and South-West Africa—was at about two-thirds of the 1943 rate. No information is available with respect to production of vanadium in Northern Rhodesia during 1944.

⁴ Preliminary.

Argentina.—Discovery of vanadium deposits near San Rafael was reported at the First Industrial Mining Congress in San Juan, Argentina. The ore is said to contain 8 to 10 percent V_2O_5 .¹⁵

Canada.—Further information concerning the occurrence of vanadium on Quadra Island, about 100 miles north of Vancouver, has been made public.¹⁶ Although this and other small deposits in the vicinity have not proved to be commercially important, their existence has been cited as a guide to the possible discovery of other richer sources.

Germany.—German requirements for vanadium, reported as 660,000 to 880,000 pounds in the form of ferrovanadium,¹⁷ in 1937, were formerly met from imported materials, such as Otavi ores from South-West Africa and vanadium slags of the Christiania-Spigerverk, Norway. In addition, vanadium was recovered in Germany from minette ores of France and Luxemburg as well as from iron ores mined in Germany itself. Vanadium-bearing flue dust and possibly red mud from the Bayer alumina process have provided auxiliary sources. Territorial losses during 1944 no doubt cut deeply into Germany's vanadium resources. It is not known to what extent Swedish iron ores continued to be available to Germany, but one estimate¹⁸ has placed a theoretical recovery of vanadium at 500 tons, if Swedish ores were used exclusively in Bessemer plants.

The following notes on the use of vanadium in German matériel are abstracted from a metallurgical study of enemy ordnance, published in Metal Progress.¹⁹

Great variability was shown in the use of molybdenum and vanadium in projectiles. * * * Vanadium was either absent, or at anything up to 0.20 percent; sometimes this amount of vanadium and an appreciable amount of nickel were present together. * * * The same shell might have vanadium but no molybdenum in the cap; no molybdenum or vanadium in the tip; and 0.20 percent molybdenum but no vanadium, or both molybdenum and vanadium in the base—or any other combination. It seems as though the Germans liked to use molybdenum or vanadium, and perhaps would prefer both together, and used them when they were available, but got along without them when they were not. * * * The use of vanadium in these projectiles is spotty. Some iron ores which have been available to the Germans carry small amounts of vanadium, most of which is recovered from the pig iron by slagging off in a converter or mixer. The vanadium is recovered from the slag by special methods that must make the metal very expensive in man-hours. The supply of vanadium from this source probably fluctuates, and this fluctuation may account for the erratic way in which it appears or fails to appear in the finished steel. When it does appear it is often in a surprisingly high amount for the type of steel under study. * * * The general use of molybdenum in what we would term high proportions and the occasional lavish use of vanadium suggest that the Germans have very adequate supplies or stockpiles of tungsten for high-speed tool steels and carbide tools.

*India.*²⁰—Vanadium is not known to be produced in India, but deposits of vanadium-bearing titaniferous iron ores occur in Singhbhum and adjacent parts of Mayurbhanj. The vanadium content is said to be as high as 4 percent (V_2O_5 ?) and reserves are placed at between 2,000,000 and 3,000,000 tons. Vanadium recovery from these ores is being investigated.

Northern Rhodesia.—Production of fused vanadic oxide by the Rhodesia Broken Hill Development Co. "proceeded satisfactorily" throughout 1943, according to the annual report of the company.

Peru.—Until surpassed by the United States in 1941, Peru was the leading vanadium-producing country of the world. The famed Mina Ragra property of the Vanadium Corp. of America, high in the Andes, has been an important source of vanadium for many years. As supplies of high-grade shipping ore diminished, an increasing proportion of shipments has been in the form of concentrates. Completion of a 200-ton plant for the production of "red cake" was retarded by labor shortages, and although reported to be virtually complete in October its operation had not commenced at the end of 1944.

*Sweden.*²¹—Considerable effort has been directed toward the development of vanadium and other alloy-metal resources in Sweden. A small percentage of vanadium is present in low-grade titaniferous iron ore at the Smaland Taberg mine in Jönköping County, which was reopened following a long period of idleness. In 1943, the Södra Ulvön mine (Västernorrland County) was expected to produce 100,000 tons of titaniferous iron ore having a vanadium content of 0.4 percent. Vanadium is also present in oil shales that are being exploited. The discovery of a deposit of vanadium ore has been reported at Vaedungsfjället, not far from the Norwegian border, in Jämtland County.

U. S. S. R.—According to a paper by A. P. Vinogradov,²² presented before the Russian Academy of Sciences in May 1944, a semicommercial plant is producing ferrovanadium from asphalt obtained from Ural petroleum. As much as 43 percent vanadium is said to be present in the ash.

SUMMARY

The status of tungsten has shifted from a material insufficient to meet requirements to one in adequate supply, and throughout 1944 tungsten ore and concentrates, ferrotungsten, and most tungsten products were free from allocation control by the War Production Board. Because of the improved supply position the Metals Reserve Company on April 30, 1944, discontinued its premium price for domestic tungsten and suspended operations at the Salt Lake City (Utah) re-treatment plant. This action was followed by the closing of a number of mines. There was also a reduction in operations of two of the largest producers. Chiefly for these reasons the 4-year uninterrupted gain in production, which reached an all-time high of 12,055 tons of 60 percent WO_3 (revised figure) in 1943, declined to 10,259 tons in 1944. Production was maintained at the high monthly rate of about 1,200 tons during the first 4 months of 1944; in fact, nearly half of the total output in 1944 was produced during this period. Thereafter, monthly production declined almost uninterruptedly, and in December 1944 it had dropped to about 400 tons. The Yellow Pine mine in Idaho retained first place as a producer of tungsten concentrates in 1944. The importance of large mining and milling units in the tungsten industry is shown by the fact that four operators, each producing over 1,000 tons, supplied 72 percent of the entire output in 1944. Domestic production was equivalent to only 51 percent of United States consumption in 1944.

Receipts of imported ore and concentrates were 19,164 short tons (60 percent WO_3 basis) in 1944, a decline of 2 percent from the all-time record of 1943. Supplying 50.5 percent of the total, Bolivia was the chief source of imports in 1944. Argentina (12.4 percent), Brazil (11.7 percent), and China (19.4 percent) supplied most of the remainder.

Consumption of tungsten concentrates in 1944, amounting to 20,100 short tons (60 percent WO_3 basis), was only slightly less than in the peak year 1943.

The supplies of tungsten ore and concentrates made available in 1944 again greatly exceeded requirements; as a result, stocks (including secondary concentrates and milling ore) were 43 percent greater at the close of 1944 than at the end of 1943. Moreover, stocks at the end of 1944 equaled about 1½ years' requirements at the rate of consumption in 1944.

Statistical statistics of tungsten ore and concentrates in the United States, 1940-44, in pounds of tungsten

Year	Production ¹	Shipments from mines ¹	General imports (receipts)	Consumption	Stocks at end of year			
					Consumers and brokers	Producers ¹	Government stock pile ²	Total
40...	4,572,806	5,062,199	9,666,228	9,955,000	2,803,249	93,618	5,417,000	8,313,867
41...	6,420,303	6,249,945	13,152,716	16,699,000	2,404,876	263,626	8,117,000	10,785,502
42...	8,977,575	8,882,403	15,409,814	17,389,000	3,416,438	355,864	9,532,000	13,304,302
43...	11,472,985	11,368,295	18,678,426	19,313,000	2,459,246	458,586	21,058,000	23,975,832
44...	9,763,695	9,785,585	18,238,897	19,165,000	1,510,419	435,634	31,867,000	33,813,053

¹ Primary concentrates.

² Stocks for 1940-43 comprise primary concentrates only; those for 1944 comprise primary and secondary concentrates and milling ore.

³ Revised figures.

Figure 1 shows trends in domestic shipments, imports, and prices of tungsten ore and concentrates since 1915.

POSTWAR OUTLOOK

When the need arose in 1941 to conserve tungsten in alloy steels, it was displaced to a substantial extent by molybdenum. However, upon removal of the restrictions on the use of tungsten on December 30, 1943, the result was an immediate swing back to prewar metallurgy for tool steel compositions. According to Spaulding,¹ "Tungsten high-speed steel, which had been largely replaced by molybdenum types, came rapidly back into favor until in a few months the molybdenum high-speed steels were again in the minority position."

Nevertheless, molybdenum-type steel, especially the so-called "6-6" (6 percent molybdenum and 6 percent tungsten) tool steel, will undoubtedly retain certain of its gains. According to Allen:²

Under the lead of the three largest motor companies, a plan has been developed to standardize on the 6-6 or molybdenum-type high-speed steel for the bulk of tool requirements, instead of the former 18-4-1 (18 percent tungsten, 4 percent chromium, and 1 percent vanadium) type. Basic reasons for the standardization are economic, the 6-6 steel being about 10 cents a pound less costly than the 18-4-1

Molybdenum-type tool steels, however, have to be especially heat treated, and many of the smaller users do not have the facilities for doing this. These consumers therefore will revert to using tungsten-type tool steels.

The use of tungsten carbide and of stellite (a cobalt-chromium-tungsten alloy) for cutting tools, which increased rapidly during the war, is expected to continue to develop.

In general, although no new uses applicable to peacetime were developed for tungsten during the war, its properties are so unusual that it is expected to recover most of its peacetime applications after the war and to expand steadily in use.

To what extent the United States will supply its needs for tungsten after the war will, of course, depend much upon the price. Stimulated by increased needs and higher prices, domestic production gained phenomenally during the war. However, upon withdrawal of the premium price paid to certain producers by the Metals Reserve Company, the high-cost operating mines were closed. Nevertheless, certain well-equipped domestic mines are likely to continue producing after V-J day, and their combined output should make the United States less dependent on foreign ores than before the war, provided of course that the present duty is not substantially reduced. Despite the duty, however, postwar domestic production, as in the past, will probably be inadequate to meet home demands, and imports will be necessary. For several years before World War II, China and the Malay States were the chief sources of imports of tungsten into the United States; and economic factors, such as size of deposits, richness of ore, and production costs, favor these countries to regain their prewar market in this country. With regard to South America, where production was increased greatly in World War II as in World War I, it is likely that the postwar output will follow the pattern after World War I and decline substantially. Nevertheless, more South American mines probably will be capable of producing tungsten at the world price after World War II than after World War I.

GOVERNMENT EXPLORATION

In 1944 the Geological Survey investigated and mapped about 150 tungsten deposits in the United States, including revisits to operating properties previously mapped. Tungsten deposits were also examined by Survey geologists in Mexico. The Bureau of Mines continued its exploration program on tungsten deposits in the United States.
